In this regard, Bauman reported that 80 percent of female virgins said they would not have intercourse even if a "perfect" contraceptive were available. He said his findings suggested that "the distribution of contraceptives on the campus will not produce widespread loss of virginity and promiscuity and it will not cause breakdown in the moral structure" (10). Findings such as Bauman's should do much to allay the apprehension of school officials about providing counseling and information programs. Our data also suggest that a careful evaluation of the reason for the occurrence of the pregnancy is important, since motivational factors of the kind we have described undoubtedly contribute significantly to the high recidivism rate associated with pregnancy among adolescents.

Finally, the psychological test data seemed to indicate that young women seeking abortion are no more neurotic as a group than nonpregnant girls their age, which suggests that time-consuming and expensive psychiatric evaluations can be dispensed with in all but a few instances. The necessity for these evaluations has often delayed the operative procedure. Routine evaluation of these patients also places a considerable load on already overloaded psychiatric facilities; it does not seem warranted in view of the many unfilled needs for mental health services.

The Mystical Experience as a Suicide Preventive

BY PAUL C. HORTON, M.D.

Three suicidal adolescents suffering from schizophrenic reactions developed the ability to conjure up a mystical consciousness. Directly experiencing this "oceanic" state (or just its memory) provided the patients with a reliably soothing safeguard against their overwhelming loneliness and possible suicide. Recognition by the psychiatrist of the mystical state as a transitional phenomenon points the way to the most effective therapeutic stance.

> The world, with all its beauty, its happiness and suffering, its joys and pains, is planned with the utmost ingenuity, in order that the powers of the Self may be shown forth in manifestation.
>
> —ANNIE BESANT (1)

IN THE LAST TWO DECADES there has been a many-disciplined resurgence of interest in mystical and psychedelic states. Various explanations have been offered to account for this important change in Western society. Disillusionment with science (2), the decline of orthodox religion (3), a neoromantic denial of the validity of human culture (4), and a lack of socially relevant myths (5) are among the proposed sociological determinants. The purpose of this communication is to call attention to one function of the mystical state: its role as a suicide preventive. The function of such an experience appears to be extremely complex and variable among individuals. Bowers and Freedman (6) have indicated, for example, that the mystical state may function as a suicide precipitant. They also point out, however, that "the utility of such insight, the extent to which it is delusional or adaptive, varies not only in psychotherapy but in psychoses, drug states, and religious and mystical states" (6, p. 245).

I am presenting here three cases where the ability of the patient to conjure up the mystical state appeared to lessen, if not altogether abolish, the need for suicide. All three cases involved isolated, lonely, and severely depressed adolescents who had either left their nuclear family for the first time or were in the process of seeking emancipation when they had their first mystical experience. All suffered schizophrenic reactions attendant to their leaving home. None was in psychotherapy at that time. Two of them made more than one serious suicide attempt; the third had suicidal ideation and, although a conscious attempt was never made, he frequently placed himself in life-threatening situations. He also managed to suffer repeated gratuitous physical injury.

Thus there was in all three cases a definite pattern of self-injury in the face of threatened loss of symbiotic attachment. The three individuals learned to achieve repetitive mystical states (two of them with the assistance of hallucinogens), which they came to seek under stress. After acquiring this ability, none of them went beyond a suicide gesture to an actual attempt.

CASE REPORTS

Case 1. This intellectually brilliant and artistically creative 20-year-old girl was an only child born to parents in their late thirties. The patient's father was an academically ambitious and narcissistic man who remained aloof from his wife and child. There were over a dozen changes of address during the patient's school years, all in connection with her father's professional advancement. As a result, the patient had no opportunity to establish lasting and stable relationships with peers or adults other than her parents. The patient's mother resented her husband's disregard for her daughter's and her own feelings but was so conflicted about her sexual and maternal roles that she was unable to set limits. Consequently, she was grossly devalued by her husband and was an unsuitable identification figure for her growing daughter.

The patient, lonely and isolated, developed an imaginary companion when she was five years old. She kept this companion until she was in her early teens. There were many other transitional objects such as stuffed animals, pets, myths, fairy tales, and music, which helped to alleviate her loneliness. In fact, a large part of the patient's entire life had been spent in the transitional mode of experiencing.

When the patient was 17, she left home for the first time to study abroad. These were months of desperate loneliness; other than for her transitional objects, she had come to depend almost completely upon her parents for companionship and affection. An overwhelming sexual experience with a middle-aged man who reminded her of her father increased her sense of isolation and unworthiness. In a subsequent moment of frenzied loneliness the patient entered her first mystical state. She was astonished by this utterly fulfilling and infinitely varied inner experience. At first tentatively, then desperately, she sought to reexperience the inner "explosion." Unfortunately she discovered a "barrier" and a month later jumped off a building, breaking her back and nearly killing herself. She had experienced a complete upheaval of her personality that made it impossible for her and her parents to continue their previous symbiotic mode of relating.

After recovering from her first suicide attempt, the patient resumed her desperate search for her inner object of devotion.

Dr. Horton was a resident in psychiatry at the Yale Psychiatric Institute when this article was written. He is now with the United States Navy in Philadelphia. Reprint requests should be addressed to Dr. Horton at the Department of Psychiatry, U.S. Naval Hospital, 16th St. and Pattison Ave., Philadelphia, Pa. 19145.

The author wishes to thank Drs. Henry Coppolillo and Peter Martin for their consultation in preparing this manuscript.

Several other suicide attempts (wrist scratching and drug overdosages) were made along the way as she entered psychotherapy and experimented with heterosexual and homosexual relations. Her first trip with mescaline, however, reopened the doors to her inner life and she reacted with: "Oh, my God! I've been here before." This was in reference to her first mystical state. Thereafter she became able to produce, largely at will, an inner state reminiscent of her first experience. Buttressed by this inner awareness she reentered psychotherapy. Unfortunately, she was unable to share this experience with a succession of therapists.

Case 2. A highly intelligent and sensitive 18-year-old boy had struggled most of his life to fulfill his father's extraordinary expectations. His father, a poorly integrated obsessive compulsive with strong unconscious homosexual yearnings, was bitterly disappointed with his own life and sought to relive it through his son's accomplishments. The son had not disappointed him until he left home for college and began to make choices of his own, particularly heterosexual ones. Boundaries between the two were poor and the father became panicky over the separation. Failing to persuade the boy to attend a neighboring university, the father mobilized the extended family to bring pressure to bear. This too failed and then the father's financial support was withdrawn. The son, conscious of the desperate struggle, resolved to separate. He managed to procure enough scholarship and loan money along with part-time work to maintain a financially independent existence. Emotionally, however, he was still very much tied to his family and suffered anxiety and depression of psychotic proportions.

During the ensuing months the patient had several automobile accidents as a result of high-speed, reckless driving; he barely escaped serious injury. A painful skin disorder requiring medical intervention was neglected. He badly lacerated his foot running barefoot through a field full of broken glass. He drank heavily, ate poorly, and lost much weight. This overall pattern of self-injury recapitulated the sixth through eighth years of his life when his parents were on the verge of divorce and were unable to show him much affection; numerous "accidents" and illnesses served to draw their sympathetic attention to him. There was one very serious "accident" that was probably a suicide attempt; the patient was unable to be sure of this due to the retrograde amnesia resulting from a trauma to his head.

Unable to retain his son in a symbiotic union, the father decompensated. He harassed the boy with every means at his disposal. He attempted, for example, to have the boy dropped from school due to "mental illness"; he sought a court order to force his minor son to return home; on one occasion he became physically assaultive; he made anonymous phone calls to his son, remaining silent on the line; he sent him unsigned "sympathy" cards; he attempted to drive his son's friends away by telling them how "ill" and "dangerous" he was. Under these pressures the patient developed a distinct, uncanny sense of "someone" looking over his shoulder and following him everywhere he went. Utterly terrifying nightmares plagued his sleep. The quintessence of these nightmares was a sense of complete annihilation that he would have difficulty shaking off for days at a time.

Far from home, lonely, afraid of and for his disturbed father, he began to pray. At first he recited prayers his mother had taught him. Finally, he just meditated by "clearing his mind." One night, exhausted and defeated, having nowhere to turn for solace, he had his first mystical experience: "It was like a fountain bursting forth. I felt a part of everything. And I died. When it stopped, I was changed. I felt limitless courage and strength and I was inspired to do great things. I wanted my life to become a continuous celebration of what I had found within." A few weeks later he was visited by a friend who had not seen him in several months. His friend was astonished by a profound change in the patient and told him: "If I didn't recognize your features, I wouldn't have known who you were. You are completely different. There is something about you—I can't say exactly what—that wasn't there before." The patient was able to resist his father's attempts to draw him back into the family circle, his reckless and impulsive behavior diminished, and he was able to seek out psychotherapy. Recurrent mystical states (not shared with his first therapist) gave him the "courage and strength to go on."

Case 3. An 18-year-old girl, the fifth of six children, had been deprived too early in life of a symbiotic attachment to her mother. Her insecurity was evident in her thumbsucking and bed wetting, which continued until she was 12 years old. Stuffed animals, pets, a blanket, and other transitional objects were in prominent usage until the patient was well into her teens. An additional instance of her transitional mode of existence is suggested in her description of her early religious training:

> I was brought up on what was a good dose of "religion." Church and Sunday school every Sunday, youth group once a week, religious instruction classes during grade school, Bible school in the summertime, Bible drills at home—I even taught Sunday school during my high school years, and I went to a Bible-centered college.

She enrolled at a distant college and began decompensating "out of sheer loneliness." She sought refuge in hallucinogens, which merely exacerbated her confusion and sense of loneliness:

> A major turning point came in my life January 15, 1969, when I mixed LSD-25 with alcohol. Bingo! I flipped out fast; it was hellish. . . . I even went so far as to try to kill myself. The only truth I knew was that I was, indeed, in a hopeless situation. Every other thought in my head was utterly distorted and warped.

A psychiatrist was unable to help her, and other suicide attempts followed. She said:

> Just to give you an idea how utterly alone I was in the madness of my mind, even since recovering, I still can't find a human being who has or could feel the pain, the fear, the hopelessness, nor aloneness, I felt then.

It was then that she experienced her "conversion":

> I remember looking around at the moment I understood I was forgiven past, present, and future, and saying, "Is that what it is? Oh, is that what it is?" How did I feel? Like a huge knot had been untied inside my head. For the first time in two months, I slept soundly and peacefully; without fear; I was filled with warmth and love for a living God.

In the subsequent two and a half years the patient has been a productive member of a campus religious organization and has made no further attempts on her life. Though still quite depressed, she appears to be continuously improving her life situation.

DISCUSSION

It is not the purpose of this communication to enter

into the complexities of the patients' therapies nor to elaborate upon the genesis of their mystical states. Suffice it to say that suicide or self-injury represented to them a way of attaining an absolute peace; the suicide wish appeared to be a product of the desire to return to the seemingly eternal safety of the warm, silent uterine world. Our understanding of primary narcissism and its forms and transformations makes it clear that the intrauterine mode of relating, characterized by passive receptivity, is an indelible part of the human psyche. Freud said, for example: "Thus we are entirely willing to acknowledge that the 'oceanic' feeling exists in many people and we are disposed to relate it to an early stage in ego-feeling . . ." (7). Kohut pointed out that "there remains throughout life an important direct residue of the original position [primary narcissism] . . ." and that the "oceanic feeling . . . is experienced passively . . ." (8). In a more metaphysical vein, Marti-Ibanez wrote: "The shadowy, formless, silent abyss of Nirvana is a state the mind could never comprehend without the subconscious memory of the uterine abyss" (9).

In reviewing the cases presented here, I am suggesting that residues of primary narcissism may represent the human being's last refuge in life's storms—short of suicide. Schizophrenic and borderline individuals sometimes imagine, perhaps erroneously, that suicide will return them to a state of mind equivalent to primary narcissism. They are often unable to carry on the sort of internal dialogue that made Hamlet hesitate. In any event, one alternative to suicide may be the mystical state: the oceanic experience that seeks, as Freud supposed, "to reinstate limitless narcissism" (7).

In each of the cases presented, there was a history of one or more extremely intense initial oceanic experiences. Numerous attenuated experiences followed; these were largely under the patient's control. Vague reverberations of the experience inspired hopefulness. Suicide attempts and other flagrantly self-injurious behavior disappeared. The patients then sought psychotherapy. Thus the ability of the patient to conjure up the mystical state came to be a safeguard against overwhelming loneliness and resultant suicide.

THERAPEUTIC IMPLICATIONS

Many psychiatrists recognize the importance of taking a special therapeutic stance vis-à-vis the mystical experience (6, 10–13). Bowers and Freedman stated: "It seems apparent that the reaction of the therapist or other significant persons in the environment could crucially affect the course and resolution of such states" (6). Braceland (10) and Kelman (11) called for recognition by psychiatrists of the validity of man's spiritual nature as a therapeutic ally. Dean (12) encouraged the development in patients and therapists of an awareness of the "ultraconscious." Eisenbud (13) gave many examples of how recognition of transcendent modes of communication (the "PSI Hypothesis") provides the therapist with greater clinical and theoretical leverage.

I have found it useful to regard the mystical experience as (among other things) a potential transitional phenomenon. Thus I treat it as a reliably soothing inner experience with maturational potential (14, 15). I do not regard it as simply another manifestation of the patient's "craziness": a delusional network to be untangled (as has been suggested to me by some of my colleagues). All of the patients described here had been in treatment with psychiatrists with whom their mystical experiences were not shared. Two of them felt that their previous psychiatrists were either inimical to the experience or "just not interested." This may or may not have been the case; in any event, all three patients had deep and abiding fears about the potentially "crazy" nature of their mystical experiences and were alert to any sign from the therapist that he too did not approve. In two of the cases, my acknowledgment with the patient of the very special character and centrality of the experience led to its accessibility for therapeutic purposes. For this reason the therapist would in my opinion be ill-advised to aggressively challenge the reported mystical state.

Winnicott said of the transitional object: "Its fate is to be gradually allowed to be decathected, so that in the course of years it becomes not so much forgotten as relegated to limbo" (15). The same is true, one can hope, for the mystical experience insofar as it serves as a suicide preventive rather than as part of a healthy religio-philosophical life-style. The therapist can best facilitate this decathexis by himself becoming a transitional object, thereby providing a reliably soothing, nurturant, reality-oriented relationship.

Aggression and Social Synergy

THE VIOLENCE ABROAD IN THE LAND is restricting living space. The variety and increase of aggression inflicted upon the citizenry at this presumably late stage of civilization require no documentation. The trend is toward direct action, with many a basal ganglion tuned for combat.

René Dubos's design for living (1) that would provide the opportunity for invigorating walks in a pleasant and unpolluted atmosphere is beyond conceiving. Better to bolt the doors and stay off the streets, although it remains relatively safe to sally forth ensconced in a ton of steel, and safer still in these chargers with doors secured. But the automobile has become part of the problem, as indicated by the mounting mayhem rendered by knights of the road in their twentieth-century armor. Destructive forces are ubiquitous (2) and deserving of consideration in debate about the human condition. The pressing questions are: Why is aggression a prominent feature of society today? and What can be done about it?

In his fascinating book *The Human Agenda* (3), which I will excerpt liberally (by courtesy of author and publisher), Gorney develops the thesis of *social synergy* as best oriented to reduce the burgeoning aggression that plagues us. He marshals the evidence that violence is learned and not innate or instinctual as Lorenz (4), Dart (5), and Ardrey (6) would have us believe.

The anthropologist Ruth Benedict (7) spoke of cultures with low synergy as those where a social structure provides for acts that are mutually opposed and counteractive, and of cultures with high synergy as those where there is social provision for acts that are mutually reinforcing. Building on the work of Benedict in comparative sociology and Abraham Maslow's elaboration of it (8, 9) the conclusion emerges that societies where nonaggression is conspicuous have social orders in which the individual by the same act and at the same time serves his own advantage and that of the group. *Nonaggression occurs not because people are unselfish and put social obligations above personal desires but because the social arrangements make these two identical.*

Benedict showed that human societies with low social synergy arrange their relationships so that the advantage of one individual becomes a victory over another, whereas in societies with high synergy the advantage of one individual becomes a victory also for the group. Competition, the hallmark of industrial society, loses primacy in societies where social synergy is high. She also showed that a society with low synergy tends to concentrate riches in a "have" group, rather than dispense them widely. In such a society the only security lies in having more than one's neighbor. This system drives its members toward competition—one must outdo another; better yet, undo him.

As Benedict pointed out, anxiety that develops so luxuriantly in societies of low synergy is absent to a degree that seems to us incredible in those of high social synergy. Goodwill is preeminent in the latter, and murder and suicide are rare or actually

In this section, the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

unknown since the universe is not seen as threatening and one does not have to snatch and grab to maintain oneself. Benedict was working with an assortment of so-called primitive societies, and we need to know if her work on social synergy and aggression is applicable in Western society.

In *The Human Agenda*, Gorney marshals evidence that it is. In examining the work ethic, which was crucial in the Benedict study of aggressive and nonaggressive societies, the alienation is not so much due to what Karl Marx noted as the stifling of the individual's potential by techniques to make production more efficient; rather it is scarcity that causes the alienation. In Gorney's thinking, humans were so driven by scarcity that they were not free to develop a psychically intimate relationship to work. He gives much evidence that competition is highly correlated with aggression. Equanimity is fostered by being paid for what one likes to do.

Only currently, in the new era of abundance, is there a possibility that the majority will no longer be driven by survival needs and alienated from work. They will have the opportunity to select the sort of activity that yields the award of self-validation. The only way to secure the self-validative benefits with work is to do work that one wants to do without the compulsion of necessity. Of course, it is quite possible in these times for a person to be engaged in both types of work—a job to make a living and likely to be temporary, and at the same time work he likes to do and that will afford the opportunity for continuing growth and advancement, in other words self-validation. Bilateral occupation is seen particularly in young people working toward a profession, often in a supporting job while they are going to school.

The central fact of today's human revolution, as developed by Gorney, is that we are leaving the old era of scarcity for a new era of abundance, so that we are faced with the outmoding of the entire fabric of values based on scarcity. Young people increasingly reject as inauthentic and hypocritical institutions that they perceive as currently following obsolete values instead of those pertinent to present reality. One of the latter is a way of life that permits people to satisfy individual needs and those of the group by the same acts, characterized in general by Benedict's term "high synergy."

Competition and aggression are far less significant in the history of the relationships of all living creatures than are cooperation and love. The time has arrived when all human beings in their work, love, and play can shift from their central social functions of assuring survival to their crucial psychological function of promoting optimum growth of human personality. One must agree with Gorney that we need to foster the kind of personality that surveys its place in the human agenda and lovingly sets about raising human life to new levels of consciousness and joy while maintaining the grace and courage to live without final certainty.

We are at the stage of social and economic development where human values must be guided to assure man's survival. Surely mere observation, documentation, and repression of the aggression that has come to the fore is not the way of survival.

Dr. Aring is Professor of Neurology, University of Cincinnati College of Medicine, and Director, Department of Neurology, Cincinnati General Hospital.

BRIEF COMMUNICATIONS

The Effect of Financing on Psychiatric Care

BY ROBERT W. GIBSON, M.D.

There will probably not be a single system of payment to physicians under national health insurance, but it seems likely that the option of obtaining care through an organized system such as a health maintenance organization will be mandated. The author discusses the pros and cons of such organizations and how mental health services might operate within them. He urges psychiatrists to assume an active role in determining what psychiatric services are needed in this country and how they can best be delivered.

THE PAYMENT MECHANISM is increasingly being used to bring about changes in the health care delivery system. Thus our interest in how psychiatrists will be paid in the future should not be limited to the monetary impact. Of equal or even greater significance are the implications for the future practice of psychiatry.

The most familiar method of payment in this country has been the fee-for-service method. Under this arrangement the patient has a free choice of physician, who then determines what services are needed and what he will charge. This essentially private transaction has some influence on the practice of medicine but it is highly variable and impossible to control in any systematic way.

With the increasing role of third-party payers has come a greater potential for the fee-for-service payment to influence the health care delivery system. Third-party payers can define benefits, set standards, and impose requirements on providers in as much detail as they choose and to the degree that their subscribers will tolerate. As health insurance programs have grown in size, the influence that the third-party payer may exercise has increased. Third-party payers have been reluctant, however, to utilize this power. After all, they must satisfy their subscribers and are to a degree dependent upon the providers.

Read at the tenth western divisional meeting of the American Psychiatric Association, San Diego, Calif., October 5–8, 1972.

Dr. Gibson is Medical Director, Sheppard and Enoch Pratt Hospital, Towson, Md. 21204.

The federal government, sensitive to the possible charges of socialized medicine, has moved rather cautiously into the field of controlling the health care system. For example, in the Medicare legislation (Title 18 of the Social Security Amendments of 1965), the very first sentence states: "Nothing in this Title shall be construed to authorize any Federal officer or employee to exercise any supervision or control over the practice of medicine or the manner in which medical services are provided. . . ."

Health insurance programs have typically provided limited or no benefits for psychiatric treatment. Thus, third-party payers have had less influence on psychiatric care than they have had on health care generally. Coverage for outpatient psychiatric care has been especially meager, so most psychiatrists in private practice, at least until recently, have experienced relatively little outside pressure on their practice.

As one reads the legislative proposals and the rhetoric of national health insurance, it is clear the mood has changed; there is no disclaimer such as appears in the Medicare legislation. On the contrary, the advocates of most of the proposals forthrightly assert that it is their intent to make drastic changes in the health care delivery system. It would be tempting to digress here to debate the criticisms of the health care system, the sources of the problems, who is to blame, what changes should be made, and so forth. But I want to avoid that in order to concentrate on the process through which financing affects psychiatric care rather than on the content of the proposals.

In varying degrees all of the national health insurance proposals advocate change: better planning, better coordination, cost containment, and a mechanism for exerting continuing control of the health care system. There is, however, no significant support for establishing a national health service under which the government would own the facilities, hire the personnel, choose the locations for dispensing care, and pay through taxation whatever costs this requires. Failure to pursue this route is not dictated just by political necessity; there is genuine fear of the problems and abuses that can occur in the large bureaucracy of government medicine.

Thus the strategy has become one of devising a scheme

of incentives and disincentives to influence patterns of practice. Put very simply, the technique is to make it economically advantageous for a physician to do what someone else thinks he ought to be doing and disadvantageous for him to do those things which someone else thinks he should not be doing. Such approaches can have only limited impact because physicians are influenced not only by economic considerations; they are strongly motivated by ethical considerations, intellectual and scientific curiosity, the attitudes of their peers and professional groups, and a dedication to human service.

The forces involved in changing the health care system are complex and dynamic. In particular we must reckon with the political process. For example, the proponent of a particular piece of health care legislation, while he believes in the merit of his proposal, may also be utilizing the proposal as a campaign issue in his quest for high office. And for every identifiable force there tends to develop a counterforce, and the end result is difficult to predict.

There will probably be no single system of payment. "Monolithic" is a bad word; "pluralistic" is considered an essential characteristic for solutions to the diverse problems of our society. In many instances, however, the emphasis on pluralism is used to reassure the individual whose mode of practice is under attack. Nevertheless, it does appear that many options will be available, although some will be more attractive than others.

ORGANIZED DELIVERY SYSTEMS

If we accept the premise that the payment mechanism is going to be used as the main instrument to accomplish change, then it is essential to know which way the winds of change are blowing. With no unanimity on any issue, the outcome is bound to be a complicated compromise of diverse points of view. There does appear to be consensus that the consumer should have an opportunity to get his treatment through an organized health delivery system offering a comprehensive range of services for a fixed prepayment on a per capita basis. One such approach is the health maintenance organization; there are many others such as health care corporations and health service organizations; also, a community mental health center can qualify as an organized delivery system.

Most proposals would require the large purchaser of health services such as an employer or government to offer subscribers a health care organization option. Many proposals provide financial incentives for this by making the benefits greater when they are received through an organized delivery system. For example, H.R. 16154, a bill "to provide adequate mental health care and psychiatric care to all Americans," requires benefits for "mental health care or treatment which is of an active preventive, diagnostic, therapeutic, or rehabilitative nature, except that the number of such visits for which payment may be made during any benefit period shall not exceed twenty unless the physician to whom the visits are made is participating in a group health program approved by the Secretary." Obviously this is intended to encourage patients to seek treatment from such a program and to induce psychiatrists to become providers in such a program.

Many arguments have been put forward in support of the organized delivery system. It is asserted that it will make services more accessible since enrollees are guaranteed not only primary care but a range of specialist and other services. Attempts may be made to use such a system to achieve a redistribution of manpower. But the argument given the greatest weight is the belief that, through organized plans, health care can be provided at lower cost than it can through solo practice. This will continue as a controversy for many years, but while the debate goes on there will be strong inducements offered for the development of organized group prepayment plans.

Some advocates of these plans believe that health professionals make too much money and hope to limit income through controlled salaries. But many see the size of the individual physician's salary as a minor cost factor and believe the organized system will accomplish most of its savings through better coordination, avoidance of duplication, and elimination of overutilization. They are less concerned about the specific charge for a given service and more concerned about the total costs to treat a given health problem. Obviously if a health problem can be treated earlier, more effectively, and more rapidly—or prevented altogether—there should be a saving.

The prepayment scheme, while discouraging unnecessary services, could also be an inducement to withhold needed services. While one saves money by preventing illness one can also save money by letting the patient die. In practice the withholding of appropriate treatment has not been a serious problem. By training and interest, physicians are so strongly oriented toward caring for patients that it is unlikely that they would deliberately withhold needed services. Furthermore, peer review techniques can be built into organized health programs to ensure quality care as well as proper utilization. In many plans the consumer is given a strong voice. In some instances the subscribers actually own and govern the plan so that, in effect, they employ and exercise a degree of control over the health professional.

HOW THE PROGRAM MIGHT WORK

I would like to take a closer look at how the organized health program can affect a physician's practice. The usual plan starts out the year with a set number of subscribers paying a predetermined amount regardless of the services to be rendered during the year. Obviously costs will be reduced if the plan holds down services and uses less costly services. It is hoped that this will lead to the promotion of health rather than just the treatment of illness.

In most legislative proposals there is no explicit requirement as to how physicians must be paid within such a plan. In general, however, the trend is toward a salary,

with sometimes the addition of a bonus based on the economic performance of the plan. As a new plan starts up, the services of specialists must often be on a fee-for-service basis because the number of subscribers is not sufficiently large to warrant a full-time specialist. As the plan grows there will be obvious advantages to hiring a specialist (say a psychiatrist) on a part-time basis; later the psychiatrist could be full-time and, even later, when the number of subscribers becomes sufficiently large, a department of psychiatry may come into being. A salaried psychiatrist in a plan might concentrate on consultation and diagnosis, and refer patients to private psychiatrists who have agreed to participate in the plan at a specified fee for service, to meet the plan's requirements for record keeping, to accept peer review, and so forth.

It is anticipated that within organized care systems the bulk of mental health services may be provided not by psychiatrists but by allied mental health professionals and newly emerging types of mental health workers. It is to be hoped that efforts will be made to maximize the skills and sensitivity to psychiatric problems of *all* the health workers within the program, so that mental health care becomes a part of total care. Many models will undoubtedly be tried. Careful evaluation and close collaboration will be required to find the mix in a given program that will maximize quality care, find consumer acceptance, achieve cost effectiveness, and offer satisfaction to the mental health professional.

How soon is the trend toward organized health plans going to affect psychiatrists? That depends on what legislation is passed, how well the plans work, the willingness of health professionals to participate in them, and a host of other factors. Many experts in the health field believe that within the next few decades solo practice will practically disappear and that organized health programs will become the predominant system of health care.

It is impossible to foretell, and predictions about psychiatry are especially uncertain. Typically the prepayment plans have offered only limited or even no psychiatric benefits. Current proposals vary but most have restrictions on the kinds and amounts of psychiatric services, with a heavy emphasis on short-term intervention. In some plans psychiatric treatment would amount to little more than first aid. Thus psychiatric care may lag behind in any shift toward organized health plans.

It has been argued that if psychiatrists like the status quo they should discourage the inclusion of mental health benefits in national health insurance. I cannot accept that position. There are many serious gaps in our system of psychiatric care: emergency services are seldom available; many high-risk groups such as children, the elderly, and the poor do not get what they need; and not enough is being done in the area of prevention.

If our government and our society are going to make good on their commitment that adequate health care is a right, psychiatry must assume a positive leadership role. Otherwise the discrimination and abuses that have plagued our efforts to help the mentally ill will be perpetuated. Psychiatric services will be provided in some form or under some guise, by someone, regardless of what benefits are written into legislation. As psychiatrists we are in the best position to determine what is needed, to plan how services should be delivered, and to judge their quality and effectiveness.

How psychiatrists are paid will determine how patients will be treated.

Peer Review: Prospects and Problems

BY DONALD G. LANGSLEY, M.D.

Peer review is now mandated for the treatment of all patients covered by the Medicare and Medicaid programs. Utilization of services—especially inpatient services—will be controlled as norms of treatment by age and diagnosis are developed. Psychiatrists, working through district branches, are encouraged to develop guidelines for peer review in line with a recent APA position statement. In doing so they must be concerned about protecting the confidences of the patient and about threats of litigation.

THE ENACTMENT OF THE Social Security Amendments of 1972 (H.R. 1) makes peer review a reality rather than a prospect. This far-reaching legislation covers many areas; one of the most important is the establishment of Professional Standards Review Organizations (PSROs). The law states that the purpose of the PSRO is to assure

Read at the tenth western divisional meeting of the American Psychiatric Association, San Diego, Calif., October 5–8, 1972.

Dr. Langsley is Professor and Chairman, Department of Psychiatry, University of California, Davis, Calif. 95616.

that services conform to appropriate professional standards, that payment is made only when the service is medically necessary, and that inpatient services are used only when outpatient treatment will not accomplish the purpose. By January 1, 1974, the Department of Health, Education, and Welfare will establish areas and designate a nonprofit professional organization to be the PSRO for each area. Each PSRO will be responsible for reviewing the professional activities of physicians, other health care practitioners, and institutional or noninstitutional providers. Each PSRO will determine the standards for elective admissions and may require prior approval of such admissions. PSROs will arrange for patient and physician profiles and will collect data so as to develop norms of care, diagnosis, and treatment based on typical patterns of practice in the region. These norms will include length of hospital stay by age and diagnosis as a principal point for evaluation and review.

When the system is under way, each physician treating Medicaid or Medicare patients will be required to execute a "certificate of need" if he wants his patient to receive care beyond the 50th percentile of length of stay for patients in the same age group and with a similar diagnosis. He will have to provide sufficient information to justify approval by the PSRO.

To the administrator, peer review is a way of controlling expenditures. It is a process that focuses on the utilization of health care services, highlighting the unusual hospital stay or the longer-than-average type of treatment. Although peer review embraces the concepts of both quality control *and* utilization review, utilization is easier to assess than quality. One of the assumptions in utilization review is that poor quality care will surface if the treatment is prolonged or unusual. For the most part, utilization review committees have been connected with hospitals, since inpatient treatment is far more expensive than any other modality. Review of ambulatory or office treatment is just beginning to come under consideration.

To the physician there are many concerns. He has had a history of independent practice with little interference or external supervision. Protection of the public has come from licensure proceedings, the actions of professional societies, and the threat of malpractice suits. Today, however, when health care is increasingly funded by third parties, the psychiatrist can anticipate that the fiscal issues will be increasingly visible. Psychiatry is now engaged in an educational process to demonstrate to government and to insurance carriers that it is economically feasible as well as medically necessary to provide equal coverage for psychiatric illness. As a result of the tradition of exclusion rather than equal coverage, insurance companies and government agencies have expressed concern about the cost of psychiatric treatment. They already have and will in the future want to limit the total benefits as well as the disorders for which treatment is provided. In spite of compelling evidence (1), they will continue to claim that psychiatry presents opportunities for misuse of services that need special attention and supervision. This is why peer review ought to be of particular concern to the psychiatrist.

Some groups have suggested that peer review ought not to be left to physicians. This follows the reasoning of those who say that health care is too important to be left to doctors. The proposal that there be public control or nonprofessional determination of what constitutes necessary treatment is frightening. Our concern is for the well-being of the patient rather than the economic security of the psychiatrist. One of the disadvantages of our profession is that every human being considers himself an expert in human behavior. It is not uncommon to have the layman consider himself capable of judging what is normal or abnormal behavior and how to treat it. We envy our internist colleagues because of the quantification that laboratory tests provide in diagnosis. Our own science is more subject to human interpretation. For that reason alone psychiatry is likely to be more than ever the object of scrutiny under the peer review process.

APA PEER REVIEW GUIDELINES

Peer review has been one of the major concerns of the American Psychiatric Association. A task force has developed guidelines for the peer review process.[1] The guidelines recommend that district branch peer review organizations work closely with local medical peer review organizations. In California this is already occurring: private psychiatrists have worked closely with the county medical societies for some time. These societies have been among the leaders in the foundation movement; the medical care foundation itself has often been the locus of peer review. In Sacramento County, for example, our county medical society has an active peer review process in which admissions to the hospital, when the care is being funded by Medi-Cal or certain types of insurance, receive prior authorization through a program called Certified Hospital Admission Program (CHAP). The CHAP effectively utilizes local controls over unnecessary hospitalization and unnecessary length of stay. In the Central California district branch (the Central California Psychiatric Society), we have taken the position that the peer review process can most effectively be carried on within the local medical societies; there is a close working relationship between the county medical society and the APA district branch.

No peer review process will be truly effective if each county has a committee whose determinations are made purely on the basis of personal experience or bias. If peer review is to be effective, there must be some consistency in the guidelines for such committees. More important, the peer review process should reflect current practice in the area. In brief, guidelines must be established that will reflect how psychiatrists within a given area generally treat patients with a given illness, and the job of the peer review organization (or PSRO) is to determine whether

[1] See "Position Statement on Peer Review in Psychiatry," page 381 of this issue of the *Journal*.

the proposed treatment generally falls within those guidelines. These are the procedures that H.R. 1 requires; the same approach is recommended in APA's position statement on peer review in psychiatry.

While the development of guidelines for the practice of psychiatry is more difficult than the development of those for the practice of surgery, we might do well to look carefully at the administrative procedures of our surgical colleagues. They have done an excellent job of defining what their procedures and practice are, of establishing agreement on what constitutes an acceptable standard of practice, and of ensuring that insurance plans include benefits for illnesses that require surgical procedures. They are less concerned than psychiatrists about confidentiality; it is of little concern whether an individual undergoes an appendectomy or a cholecystectomy as long as he recovers and functions as he did before his illness. In psychiatry we are only too aware of the lingering stigma about psychiatric treatment. The patient who has had psychiatric treatment may be denied the opportunity to run for Vice-President of the United States or may be denied a driver's license or may have a hard time getting into college. There are various other subtle problems associated with a history of psychiatric treatment. The content of the treatment often deals with highly charged personal data that psychiatrists feel require a high degree of confidentiality.

Nevertheless, if one takes into account the variations in practice and the need for confidentiality, similar principles can be applied to establishing criteria for psychiatric practice as for surgical practice. The first step consists of defining specifically what the psychiatrist does in his treatment. This means classifying all the acceptable treatment procedures, including individual, group, and family psychotherapy and the various somatic therapies and stipulating an appropriate amount of time or effort involved. This is the approach of the Relative Value Scale: a committee is currently working in California to establish the relative values of all psychiatric treatment procedures. The next step is to determine what treatment is used for various kinds of patients and disorders. Information on publicly funded programs is available from the California Department of Mental Hygiene, and similar information is contained in the files of various insurance carriers. But it is difficult to get information from the private practitioner. He has justifiably been concerned about releasing data concerning his patients because of the confidentiality problem. In general, he has learned to distrust government agencies and would understandably be reluctant to give data on his private patients unless he feels that adequate safeguards are being enforced to protect the patient and that also take into account his own role as a private practitioner.

In the opinion of many, the only organization in which the private practitioner will have confidence is his professional society. The Central California Psychiatric Society has voted to develop a plan to collect data on the treatment of patients by privately practicing psychiatrists. This program will be sponsored by the district branch and have access to the facilities of a university and its medical school, including a computer center and data processing equipment. We are developing a system that will protect the identity of the patient and yet will offer the private psychiatrist information about the standards of practice in his own area. From such standards of practice, general guidelines can be developed for the work of peer review organizations.

It is far too early to make any predictions about how effective such guidelines will be. But we are all aware that a system will be imposed on us if we do not develop one ourselves. We have a choice at this time in arranging standards of practice and procedures for the care of the mentally ill that will offer patients the best possible treatment. The alternative is that a government agency or an insurance carrier will develop standards without our participation. The Ann Arbor Professional Advisory Survey is one example. In that survey, the average length of hospital stay by diagnosis and age group was established from data supplied by a number of general hospitals throughout the United States. But the data included patients who were admitted to general hospital units only for processing before they were sent on to private psychiatric hospitals or state mental hospitals. As a result, the average length of stay was very short; it was clear that the figures related not to definitive treatment but rather to diagnosis, evaluation, and disposition. If standards were adopted in this way they would do a great disservice to patients with mental disorders.

NEED FOR SAFEGUARDS

The peer review mechanism must also develop safeguards for the patient and the psychiatrist. As already noted, the peer review process must be carried on in such a manner as to completely protect confidential information. Another concern is that psychiatrists serving on review committees may be sued by patients or providers. It is also human nature to expect criticism from colleagues. Perhaps such problems can be minimized by persuading the most experienced psychiatrists in the community to serve on the Professional Standards Review Organizations (PSROs) and by rotating their membership. In addition, legal safeguards against litigation must be developed. Another potential problem may arise if the findings of PSROs become the basis for malpractice actions or other suits. If a PSRO disallows a treatment procedure, can this be construed as an indication of malpractice? Does the PSRO then become the expert witness for the plaintiff? Fortunately, H.R. 1 protects the patient, the reviewer, and the records. Those providing information to a PSRO cannot be held civilly liable, nor can members or employees of PSROs be held in violation of criminal or civil law as long as due care is exercised. H.R. 1 also provides that no practicing physician will be held liable on account of an action taken in compliance with or reliance on professionally developed norms, provided he exercises due care in all his professional conduct.

Peer review is now a reality. The APA position statement on peer review in psychiatry is, in my opinion, a document deserving of close study and effective implementation by all district branches and members of the American Psychiatric Association.

A Preliminary Report on Multi-Image Immediate Impact Video Self-Confrontation

BY MILTON M. BERGER, M.D.

A multi-image closed-circuit video self-confrontation with deliberate distortion of some of the images is presented to patients for immediate impact during psychotherapy. Seeing the distorted images alongside the clear image serves to elicit free associations about past or present self-concepts and introjections, which may then lead to significant clarification and insight into the self in the here and now. The technique is not proposed as a form of therapy by itself or as a substitute for analytic psychotherapy, but rather as an adjunct to be used in appropriate contexts.

THIS IS A PRELIMINARY REPORT on a new technique, multi-image immediate impact video self-confrontation, that I have used in psychotherapy to stimulate the emergence of repressed free associations related to self-images and injunctive messages incorporated early in life. H.S. Sullivan very succinctly stated that the repeated, reflected images of our selves that we receive from others early in life determine our self-image and self-concept (1). Many other workers in psychiatry, e.g., Freud, Adler, Jung, Horney, Fromm, Kubie, Spitz, Lewin, and Ives-Hendricks, also focused their attention on the development of self, self-concepts, idealized self-image, potential self, actualized self, real self, and fulfilled self. Some, like Horney (2), developed unified theories to explain the basic anxiety and the early life experiences that not only cause alienation from self but also cause energies to be dissipated in neurotic attempts to create an idealized image of self.

Dr. Berger is Director of Education and Training, New York State Department of Mental Hygiene, South Beach Psychiatric Center, 777 Seaview Ave., Staten Island, N.Y. 10305, and Assistant Clinical Professor of Psychiatry, College of Physicians and Surgeons, Columbia University, New York, N.Y. He is also Chairman of the Video Task Force of the APA Program Committee.

EQUIPMENT AND TECHNIQUE

Through serendipity, a long-standing interest in intrapsychic and interpersonal communication systems, and some years of experience with the use of video equipment in psychotherapy (3), I recently learned how to produce a number of clear and distorted self-images in tandem for self-image confrontation.

The technique requires the following minimum equipment: one videotape recorder, two mobile cameras with zoom lenses, two monitors, one split-screen special-effects generator, and one or more microphones. I bring to the patient's attention from two to six or more partial images of himself on two or more closed-circuit monitors while these pictures are being videotaped for immediate or later replay. As they are being presented in tandem series on the monitor, the pictures intermittently become more distorted or blurred through the movement of the camera, or by my increasing or decreasing the light aperture of the lens or altering the focus, or through a combination of these (see figure 1). A patient may be lying on the couch in traditional psychoanalytic fashion or sitting up, or he may be in an interaction with members of his psychotherapy group or family during this video experience.

Through electronic means I, as the therapist, have an ability to magnify, focus on, and distort some of the pictured aspects of a patient's image, just as people do to themselves with their inner "I" and "eye." I can then play back the recording made just moments before, to produce a deeper, more complete experience and greater free association to what is triggered by seeing a clear and a distorted self-image alongside each other. There is both an enlarged, objective, observing ego at work and an expanded, subjective, recognizing, identifying self, along with increased receptive strength (4) as the patient feels "at home" with those images or pictures or aspects of self now emerging on the monitors as stimuli.

FIGURE 1

*Two Examples of Multi-Image Closed-Circuit Pictures in Tandem, with Images Ranging from Clear to Distorted**

*The author is pictured in these examples.

RESULTS

Forty long-term patients I have seen in individual and group psychotherapy in private practice, most of whom had a diagnosis of character neurosis, have had one or more ten- to 45-minute experiences with the type of multi-image confrontation described here. One 49-year-old woman, depressed and emotionally impoverished, with lifelong suicidal tendencies, stated that she had no response to seeing herself. All the other patients had free associations that were highly significant in terms of what became available for working through or for the ongoing assessment of progress in therapy. There were no immediate or delayed harmful effects, although 70 percent (28 patients) spontaneously referred to memories of the experience in the following weeks. The multi-image experience served as a marker or milestone in the way it became imprinted, and patients referred back to it at unpredictable moments.

The experience has been described by different patients as "surrealistic," "objectifying," "reflection in action," "really taking a look at myself," and "being surrounded by myself." It is seeing the shadow-like, unclear representations of self-images in tandem after a clear image that stimulates associations to deeper introjections, identifications, and incorporations. These have functioned as the inner psychic "complexes" or selves described by Jung (5) that have vexed the patient-person for so many years while remaining elusive, inconstant, and not quite palpable. Patients now have a chance to become more clearly aware of and to grasp these "personas."

CASE REPORTS

Case 1. Mrs. P., a 27-year-old sociologist who had always felt victimized, reacted with antipathy, disgust, pain, and moaning anguish to multi-images of the front of her face, although she squealed with spirited delight and self-acceptance as she turned to her left and saw images of the right side of her face. During a profound abreactive experience she then stated in her free associations that in the front views she saw the faces of her mother and grandmother in herself. She saw them as washed out, drained, depressed, old, lifeless, and really miserable, and could see and hear her mother's injunctive message to her. "Don't try to be any different than me 'cause you won't make it . . . and if you're not going to make it, don't try! Don't even bother. You'll be a sorry girl if you do."

Case 2. Miss J., a 25-year-old secretary, self-effacing and repeatedly self-defeating, sat quietly reflecting on her self-images during a group session. She murmured, "The image on the left is clear. That's probably how I seem to others, but I don't see myself that way. I see myself blurred and hazy like in the third image." When questioned as to what was threatening in seeing herself clearly, she responded, "Then I'd have to be responsible for myself."

Case 3. An alienated 32-year-old divorced account executive asked, "Is it possible to be possessed? I see my mother's face in my face on the monitor. I suddenly realize she never let me be myself. As a child I always wondered what was wrong with me because I felt confused and didn't know where and who I was."

Case 4. Mr. R., a 40-year-old detached and alienated executive with few memories up to age 12, said, "As I look at the images getting smaller and smaller, it's as if I'm going back into my childhood . . . to being nothing."

Case 5. Miss L., a 30-year-old opera singer concluding four years of successful psychotherapy, remarked, "I see the clear image as the me I am now and the ones coming up blurred as the ones of my future as I continue to develop my potential."

Case 6. Mr. A., a successful interior designer aged 35, commented on his dislike of video because he often saw the right side of his face, which he disliked. He felt it was feminine and was the "sissy" in him remaining from having grown up as a "mommy's boy." Moments later he recalled with insight and relief the fact that it was his right testicle that never descended.

Some patients were startled to learn that it is the distorted picture of the self that feels familiar and is the way they usually perceive themselves.

CONCLUSIONS

The multi-image method described here is another step in the long evolution of techniques developed to serve as adjuncts in expediting the recall of events and thought-feeling associations that can lead to catharsis, insight, and the surrender of psychosocial self-images or emotional fixations that retard growth and maturation. The technique is not presented as a form of therapy per se or as a substitute for analytic psychotherapy.

It is necessary to review and consider revision of theories of the self that regard man from a rigid viewpoint. Although there is continuity in the structural core of each person, the self is not a concrete self but is experienced as being composed of multiple layers or cores within cores (6). A maturing person is composed of many co-existing selves or self-aspects, changing and in flux from moment to moment, yet always having a unifying matrix of a physical body mass, name, gender, life history, incorporated cultural time-binding practices, language, values, and emotional reaction patterns. Each person is unique in his process of creatively synthesizing clear and distorted past and present images that are introjected and identified with as they are amalgamated into his own growing self.

Phenothiazine Deaths: A Critical Review

BY ROGER PEELE, M.D., AND IDELLA S. VON LOETZEN, M.A.

To determine whether "phenothiazine death" is a valid entity, the authors examined case studies in the literature for other explanations of these sudden, unexpected, autopsy-negative deaths. The results of their comparisons of a large number of phenothiazine deaths and deaths due to lethal catatonia raise doubts as to the validity of phenothiazine death as an entity.

DR. LUTHER BELL of McLean Asylum in Massachusetts 123 years ago presented to the Association of Medical Superintendents of American Institutions for the Insane a paper concerning ten patients who died suddenly and whose autopsies failed to reveal an adequate explanation for their deaths (1). Because of his article, the term "Bell's mania" was used to describe this entity. Later, it was more commonly called "lethal catatonia," although it was also given such other names as "exhaustion death" and "deadly catatonia."

A typical history was that of a patient who had initially undergone a personality change over a period of weeks, followed by hyperactivity, delusions, and hallucinations. This picture continued after hospitalization and, in addition, there was sometimes a high fever, more than 108F in a few cases. After several days, weeks, or months, the patient would be found dead without any advance warning (1–12). We want to emphasize that there were cases described that were at variance with this picture. Some cases were chronic, some patients did not have hyperactivity, many patients did not have hyperpyrexia, and some patients only had a severe cardiovascular collapse and did not die.

In 1956, Ayd described the hospitalization of a schizophrenic patient whose agitation was so severe that the dosage of chlorpromazine was gradually increased to 2500 mg. by the 18th hospital day (13). On the 21st day the patient collapsed, went into coma, was found to have a temperature of 108F, and died within nine hours of the collapse. Ayd attributed this death to phenothiazines, not to lethal catatonia. With a few exceptions, the literature since 1956 has seen sudden deaths as "phenothiazine deaths," not "lethal catatonia."

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with the Area D Community Mental Health Center of Saint Elizabeths Hospital, National Institute of Mental Health, Washington, D.C. 20032, where Dr. Peele is Director and Ms. von Loetzen is Research Associate; Dr. Peele is also Associate Clinical Professor of Psychiatry at George Washington University, Washington, D.C.

Deaths attributed to phenothiazines represent sudden deaths or sudden cardiovascular collapse without physical or autopsy findings that explain the death.[1] Sudden, unexpected, autopsy-negative deaths in the normal population are usually considered to be cardiac deaths. It is difficult to obtain a description of sudden, unexpected, autopsy-negative cardiac deaths in an unselected population, and the major studies on this topic do not separate those which are autopsy-negative from those which are autopsy-positive (14–16). We can say that sudden, unexpected cardiac death tends to occur in the older male, but we can only suggest that this is also true of the subgroup that is autopsy-negative.

We will make the hypothesis that phenothiazine death is not a real entity, but that it is composed of two other entities: lethal catatonia and the autopsy-negative, sudden, unexpected cardiac death found in the normal population. We will more specifically hypothesize that any difference significant at $p<.05$ between the lethal catatonia group and the phenothiazine death group can be explained by the inclusion of the autopsy-negative cardiac deaths.

METHOD

We surveyed the English, German, French, and Italian literature for cases that were called phenothiazine deaths and for cases of lethal catatonia or one of its equivalents. We eliminated those deaths attributed to phenothiazines which could be explained by a pathological finding, such as a bolus of food in the lungs. We also excluded phenothiazine overdoses.

We found 27 studies describing 65 cases of sudden death considered by the authors themselves or subsequent reviewers to be related to phenothiazines. We found 23 studies describing 94 cases considered to be lethal catatonia.[2] We compared two groups according to sex, age, month of death, diagnosis, reports of hyperpyrexia, and length of hospitalization.

RESULTS

Our investigation revealed that there was no significant difference by chi square for sex, but there was a significant difference ($p<.05$) between the two groups for age at death (see table 1).

The literature on lethal catatonia had suggested that deaths attributed to this cause were more common in the warmer months. For 48 of the cases in each of our two groups, the month of death was given. Death occurred in May, June, July, August, or September in 17 of the 48 phenothiazine deaths (35 percent) and in 18 of the 48 cases of lethal catatonia (37 percent). The difference was not significant.

TABLE 1

Comparison of Phenothiazine Deaths and Lethal Catatonia According to Sex and Age

Category	Phenothiazine Deaths (N=65) Number	Percent	Lethal Catatonia (N=94) Number	Percent
Sex				
Male	39	60	46	49
Female	26	40	48	51
Age at death				
Under 21	7	11	15	16
21–30	10	15	28	30
31–40	21	32	33	35
41–50	18	28	10	11
51–60	6	9	7	8
61 or older	3	5	1	1
Mean age at death	38 years		33 years	

Table 2 presents the results of the three remaining comparisons for the two groups. The diagnoses were found to be significantly different at $p<.05$, the highest recorded temperatures were not significantly different, and the lengths of the last hospitalizations were significantly different at $p = .001$.

DISCUSSION

Our findings were that, in comparison to the lethal catatonia group, the phenothiazine death group included more men (although not significantly so), more older patients, and patients hospitalized for a longer period, and had a broader range of diagnoses. The greater numbers of men and of older patients would tend to support our hypothesis that phenothiazine death includes two groups, lethal catatonia and autopsy-negative cardiac deaths. The greater length of hospitalization would also follow from the same hypothesis, since the older patients have had longer hospitalizations.

The broader range of psychiatric diagnoses is not surprising. The literature on lethal catatonia described sudden, unexpected, autopsy-negative deaths as occurring in catatonics or manics, and some of the diagnoses were made after the patient died. In addition, the sudden, unexpected, autopsy-negative deaths of patients who did not have catatonic or manic diagnoses might have been reported under some category unknown to us, if they were reported at all.

In a previous paper (17), we surveyed the reported phenothiazine deaths of patients who had a clinical history similar to that of classical lethal catatonia, i.e., a hyperactive period of less than three months halted by sudden, unexpected, autopsy-negative death. Most of these cases were not adequately described to permit establishing whether the case fitted the classical picture, but 18 very clearly did. When these 18 are removed from our

[1] Isolated reports of myocardial pathology have not been confirmed as the cause of death.

[2] Details on the studies examined, including a full list of references, are available from the authors on request.

TABLE 2
Comparison of Phenothiazine Deaths and Lethal Catatonia According to Diagnosis, Highest Temperature Recorded, and Length of Last Hospitalization

Category	Phenothiazine Deaths (N=65) Number	Percent	Lethal Catatonia (N=94) Number	Percent
Diagnosis				
Organic brain syndrome	7	11	1	1
Mania	0	—	5	5
Schizophrenia	32	50	33	35
Other psychoses	1	2	9	10
Other	10	15	0	—

More than a year	32	49	4	4
Unspecified	3	4	3	3

group of 65 phenothiazine deaths, one is left with a group that is even more predominantly male and a group in which the average age at death of the men is higher than that of the women. We realize this is only circumstantial evidence that the same phenomenon which strikes down the older man in the normal population has occurred in the mentally ill who are receiving phenothiazines. However, the higher average age at death for men in this group is highly unusual in the mental hospital population, where elderly women predominate. In addition, women generally have a higher average age at death.

It would appear that sudden, unexpected, autopsy-negative death in a patient receiving phenothiazines should not be attributed to phenothiazines, since there are two previously known groups in which the patient's death might be categorized: cardiac death that is sudden, unexpected, and autopsy-negative, or lethal catatonia. However, there are some unsatisfactory aspects to this conclusion, two of which we should like to mention.

It would have been very desirable to present a comparison of the clinical pictures, but a categorization that goes beyond the "hard" data that we compared in our tables would have created Procrustean beds. Both literatures, especially the literature on phenothiazine deaths, often present cases without any clinical description. When descriptions *are* given, "excitement," "agitation," and "combativeness" are frequently mentioned in the literature on both entities.

A second disappointment came from our inability to obtain an unselected series of sudden deaths in people who were autopsy-negative. Because the literature on sudden, unexpected death does not separate the autopsy-negative from the autopsy-positive, we have had to take the not totally satisfactory position that sudden, unexpected, autopsy-negative cardiac death has the same age and sexual preference as sudden, unexpected, autopsy-positive cardiac death.

CONCLUSIONS

Sudden, unexplained deaths in the mentally ill are a phenomenon that has been described for over a century, yet most of the articles in the past 15 years have attributed these deaths to phenothiazines.

This paper has compared the sudden, unexplained deaths attributed to phenothiazines with those sudden, unexplained deaths attributed to lethal catatonia according to six characteristics. There were some similarities and some differences in these comparisons and nearly all the differences could be explained on some other basis than that there is such an entity as "phenothiazine death." There is some suggestion that "phenothiazine death" includes two previously known types of sudden, unexplained, autopsy-negative deaths: cardiac deaths among the general population and lethal catatonia among the mentally ill. Although our survey raises doubts about the existence of "phenothiazine death," the possibility of its existence could not be completely disproved.

Psychiatric Assessment of 30 Chronic Users of Cannabis and 30 Matched Controls

BY MICHAEL H. BEAUBRUN, M.B., AND FRANK KNIGHT, M.B.

A study done in Jamaica of 30 chronic cannabis smokers (use for at least seven years) and 30 matched controls revealed no significant differences between the two groups in the incidence of mental illness or of abnormalities of mood, thought, or behavior. Nor did the groups differ significantly with regard to criminal records, use of other drugs, or upward or downward movement in social or economic position.

RECENT AMERICAN AND CANADIAN reports on cannabis (1–3) have stressed the need for more information about its long-term effects on chronic users. Jamaica offers a particularly good opportunity to investigate such effects, since: 1) the use of cannabis has been endemic for more than 100 years; 2) its use is widespread in the lower socioeconomic classes; and 3) there is remarkably little use of other drugs with the exception of alcohol and tobacco (4, 5).

In 1970 and 1971 a team of anthropological field workers studied approximately 2,000 people from seven areas of Jamaica. From four of these locations they identified a representative sample of 30 chronic users of cannabis and 30 matched controls who agreed to remain in the hospital for six days and nights to undergo physical, psychological, and psychiatric assessment. The subjects were matched individually for social class, occupation, income, age, and sex. Chronic use was defined as daily use over a period of not less than seven years. All of the subjects admitted to having smoked a minimum of three "spliffs" a day or its equivalent. A "spliff" refers to a mixture of tobacco and marijuana approximating the U.S. "joint" but of greater potency. A sample of the marijuana normally smoked was collected from each subject; the mean weight for each sample showed a delta-9-tetrahydrocannabinol content ranging from 0.7 percent to 10.3 percent, with a mean weight for the entire sample of 2.96 percent.

In this paper we will deal only with the results of the psychiatric examinations, which were conducted by two psychiatrists to whom the subjects were randomly assigned.

The objectives of the psychiatric assessment were as follows: 1) to look for evidence of psychosis or detectable abnormalities of mood, thought, behavior, or perception and to find any correlations of these with cannabis use; 2) to supplement the information on the subjects' life histories that had been obtained by the sociological field workers and to serve as a further check on this information; 3) to investigate the personality correlates of smokers and nonsmokers in terms of extraversion and neuroticism; 4) to examine the relationship of chronic smoking to arrests and conviction for crime, use of other drugs, and upward or downward social mobility as revealed by the life histories; and 5) to examine the relationship between parental deprivation in early life and the use or nonuse of cannabis.

METHOD

The following five forms were used: 1) a life history in narrative form, 2) a general-purpose psychiatric questionnaire precoded for computer use (originally piloted at Rockland State Hospital, Orangeburg, N.Y. (6), 3) a precoded mental status examination record (developed by Drs. Spitzer and Endicott of the New York State Psychiatric Institute) (6), 4) the short form of the Eysenck Personality Inventory, which was piloted and adapted for local use in a previous study (7), and 5) a smoking history

The authors are with the Department of Psychiatry, University of the West Indies, Mona, Kingston 7, Jamaica, where Dr. Beaubrun is Professor and Head and Dr. Knight is Lecturer.

This report is part of a larger study, "Effects of Chronic Smoking of Cannabis in Jamaica," supported by Public Health Service contract HSM-42-70-97 from the National Institute of Mental Health.

The authors wish to thank Dr. Nathan Kline for his assistance with the computerization of the data, Dr. Timothy Harding for his work on the statistics and on the data regarding parental deprivation, and Ms. Stella Beaubrun for her help in keeping the records and in coordinating the project.

schedule that incorporated questions about attitudes toward cannabis use and opinions about its medicinal and other uses.

Subjects were admitted to the hospital from Monday to Saturday and were requested not to smoke cannabis while in the hospital.

RESULTS

The main findings are summarized in table 1. Eight of the 30 smokers had a positive family history of mental illness, while only two of the 30 nonsmokers had such a positive family history. This difference is significant ($\chi^2 = 4.25$, df = 1, $p < .05$).

One smoker and one nonsmoker gave personal histories of past mental illness. Both also had family histories of mental illness. The smoker had been hospitalized for a schizophreniform illness that might have been provoked by heavy cannabis use. A positive family history of mental illness normally indicates a greater likelihood of illness in the subject. Therefore the absence of any greater incidence of illness in the smokers suggests that cannabis smoking may play a role in preventing psychosis in predisposed individuals.

Seven smokers and three nonsmokers gave family histories of alcoholism, a difference that did not reach significance at the level $p < .05$. The criteria used for arriving at a diagnosis of alcoholism in the family necessarily had to be somewhat rough and ready: Any report by the subject of a family member who drank heavily and whose work and social functioning seemed to have been disrupted by alcohol resulted in our recording a family history of alcoholism.

Four smokers and three nonsmokers were adjudged as having had problems with alcoholism in the past.

In a field survey of drinking practices in Jamaica in 1966, one of us (M.H.B.) found relatively few alcohol problems among Jamaicans of African origin and from a low socioeconomic class and suggested that ganja (cannabis) might be used as an alcohol substitute by lower-class Jamaicans (7). Prince, Greenfield, and Marriott (8) in a later study supported this view and found evidence that ganja might be a benevolent alternative, protecting poor Jamaicans from becoming alcoholics.

The figures emerging from this latter study are not sufficient to reach a verdict on this issue, but it is worth recording that two of the smokers in our study reported that they had been able to reduce their alcohol intake and seemed to relate this to cannabis use. One of them (aged 54) was the only man in the study who had started to smoke cannabis relatively late (at age 44), and he had been able to stop drinking entirely in the past four years.

Ten smokers reported having had hallucinatory experiences as compared with two nonsmokers, a difference significant at the $p < .01$ level. Of the smokers, more than half had had these experiences once only when they first began using the drug in adolescence or earlier or when they used it in pure form.

Three subjects from one area of Jamaica reported a first-time visual and auditory hallucination of a little lady dancing toward them in a fear-provoking experience that sounded like an initiation rite. The experience seemed to be exciting as well as frightening, but the subjects knew that they had only to hold their ground and open their eyes wide for the vision to disappear. They seemed to feel that they were being tested, and one subject said that his mother had told him that if his mind were not strong, he would go mad.

Ten smokers had been arrested at least once as compared with seven nonsmokers (difference not significant). In view of the fact that possession of cannabis carries a mandatory prison sentence of 18 months, this finding is a little surprising. Three of the smokers had been detained for possession of cannabis. On the whole the figures suggest no significant relationship between cannabis and crime.

The relationship of smoking to repeated arrests (two or more) was also investigated, but again the figures showed no significant difference.

OTHER MEANS OF COMPARISON

Extraversion scores on the Eysenck Personality Inventory (short form) for smokers and nonsmokers were identical (mean score of 3.75). On the neuroticism scale smokers had a mean score of 1.8 (out of a possible 6), with a standard deviation of 1.37, while nonsmokers had a mean score of 2.2, with a standard deviation of 1.88. This difference was not significant.

It was noted that the smokers were more affable and popular than the nonsmokers, though nurses and others on the ward were not told whether the subjects were smokers or nonsmokers and all of the examinations other than the psychiatric examination were conducted blind. Nonsmokers were more often identified as "neurotic" and were more often impatient or intolerant of ward routines and discipline. This effect may have been due to a difference in motivation. While all of the subjects were paid equally for their time and all seemed to value the opportunity for a physical checkup, the smokers also

seemed motivated to prove that their practice was not harmful.

No significant abnormalities emerged from the mental status examinations. Three ratings were obtained from the computer: 1) a Hamilton Rating Scale for Depression, 2) a schizophrenic rating scale, and 3) the Wing Rating Scale. Of the results obtained from these, the only abnormality shown was a mild depression in one nonsmoker.

The use of hard drugs is as yet virtually unknown among working-class Jamaicans, and it was not surprising to find that no one in the study had ever taken any narcotics, stimulants, hallucinogens, or sedatives. The only drugs used other than cannabis were alcohol and tobacco. In every instance use of cannabis was preceded by cigarette smoking.

In view of the frequent reports that the use of cannabis leads to a loss of competitive striving and an "amotivational syndrome," particular attention was paid to the subjects' work records as revealed in their life histories and the general-purpose psychiatric questionnaire. Data were carefully recorded concerning the regularity and continuity of employment and the frequency and nature of job changes. No significant differences in work record could be demonstrated between smokers and nonsmokers. It may be that a difference could have been demonstrated if our sample had included intellectual workers or white-collar workers of any kind, but in a sample made up mainly of fishermen, subsistence farmers, and unskilled or partly skilled manual workers from villages where there is relatively little mobility, such differences were not detectable.

For a more complete answer to the question of the amotivational syndrome it would seem desirable to examine samples of students or other more competitive groups.

An attempt was made to assess the quality of the subjects' early lives and to see whether parental deprivation in early childhood might be related to smoking or nonsmoking in later life. A scale of items indicating deprivation was drawn up, and interobserver reliability of the method of assessment was established. Deprivation scores in smokers and nonsmokers were found not to differ significantly (two separate statistical methods were used).

CONCLUSIONS

No significant difference could be demonstrated between the two samples in the incidence of mental illness or alcoholism or of any abnormalities of mood, thought process, or behavior; the smokers, however, had had more mental illness in their family histories and had experienced hallucinations more frequently than the controls. Such hallucinations had usually occurred once only—on first smoking cannabis.

Nor were significant differences found between the chronic smokers and the nonsmoker controls on scales for extraversion and neuroticism measured by an adapted version of the shortened Eysenck Personality Inventory. Finally, no significant differences could be demonstrated between the two groups in the number of arrests or convictions for crime, the use of other drugs, or upward or downward movement in social or economic position.

Problem Formulation: The Problem-Oriented Record

BY RALPH S. RYBACK, M.D., AND JOHANNA S. GARDNER, M.D.

The authors discuss the benefits of using a problem-oriented record (chiefly the clearer documentation of treatment, the simplification of communication among mental health personnel, and the stimulation of further research) and the problems inherent in applying this approach to psychiatric practice. Both the benefits and the problems are illustrated by means of two case reports.

THE PROBLEM-ORIENTED RECORD was developed by Lawrence Weed (1, 2) and adapted by others (3) as a logical means of transmitting and assessing medical data for the purposes of treatment and evaluation. It can be an integral part of the scientific portion of the mental health information system (4, 5). It is composed of four portions: 1) data base, 2) problem list, 3) plans, and 4) follow-up (see appendix 1). It is problem oriented in that it contains a complete list of the patient's problems and progress notes specifically related to each of those individual problems. The pertinence of this method to psychiatry has recently been reported by Grant and Maletzky (6) and Hayes-Roth, Longabaugh, and Ryback (7).

The purpose of this paper is to discuss the formulation of psychiatric problems, and the inherent difficulties of applying the problem-oriented record to psychiatry, using as an example a case in which problem formulation was performed in one way at the time of admission and then reviewed and reformulated by a consultant at a later time. Another case is briefly presented to demonstrate how a flow sheet can be used to summarize a complicated psychiatric history involving the use of several psychotherapeutic medications.

CASE REPORTS

Case 1. P.H., a 47-year-old woman, is the mother of two children. At her first psychiatric admission, which lasted three days, her *chief complaint* was an overdose of secobarbitol and amobarbitol (Tuinal); she said, "I didn't mean to harm myself."

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this paper was written, the authors were both with McLean Hospital, Belmont, Mass. 02178, where Dr. Ryback is Director of Alcohol and Drug Abuse Services and Dr. Gardner was a resident in psychiatry; Dr. Gardner is now a resident in psychiatry at Beth Israel Hospital, Boston, Mass.

The authors wish to thank Dr. Ross Grumet for his assistance with this paper.

Her *present illness* began in 1964, when she experienced two losses: her husband began a new job that involved his spending more time away from home and a valued maid left the household for personal reasons. P.H. felt angry, unhappy, "abandoned and cut off when I needed [them] most," and suspected her husband of infidelity. Her chronic symptoms of premenstrual headaches and dysmenorrhea became more distressing and incapacitating; she complained of fatigue, insomnia, weight loss, and dysuria. She also complained of heavy, painless menstrual bleeding: "finding myself floating in blood; it's an axe over my head." Repeated gynecologic, endocrinologic, and neurologic evaluations (including diagnostic dilation and curettage in 1966) were negative.

In 1969 P.H. was found to have moderately elevated monoamine oxidase levels, and the administration of oral estrogens (10 mg. of Provera and 10 mg. of Premarin) was begun. Initially she experienced fewer headaches and less depression; then the symptoms recurred. In 1970 she requested a total hysterectomy for "cure." Her two sons went away to school. She was referred to Dr. X. for psychotherapy. She began to abuse drugs (glutethimide [Doriden], Tuinal, and phenobarbital) by taking excess medication illegally procured by her husband. She was hospitalized three times for withdrawal symptoms. About a month prior to her psychiatric admission Dr. X. refused to prescribe further medication. The week before admission she took 20 Tuinal tablets over three days, became frightened of her suicidal thoughts, and sought psychiatric hospitalization.

According to her *history*, P.H. is the eldest of three children of an upper-middle-class suburban family from the Northeast. Her father is an architect, described as domineering and perfect; she described her mother as "living in a dream world, a 'yes' world in which everything was my father." She had the normal developmental landmarks and a "usual" fear of the dark. She felt her parents spoiled her and implied she couldn't function without them. She had a good academic record in college. She wanted to make dancing her career, but her parents disapproved. She married an architect who "would take care of me as my father had." Shortly after her marriage she was involved in an automobile accident; her husband was driving but was not at fault. She attributed her headaches to injury in this accident.

Physical examination revealed a scar on the right supraorbital ridge. There was no evidence of organic disease. The *mental status exam* revealed a seductive appearance, no evidence of thought disorder, depressed affect, and limited insight into her illness. Her full scale IQ in psychological testing was 116, with no verbal-performance discrepancy. She was seen as narcissistic, with poor frustration tolerance, transitional object relationships, and a hostile-dependent attitude ("biting sarcasm") toward men, whom she either idealized or devalued.

The admitting physician formulated the following problem list, which he divided into psychiatric, social, and organic problems:

Psychiatric: 1) infantile narcissism, 2) seductiveness, 3)

TABLE 1
Problem List Developed by Consultant for Patient P.H. (Case 1)

Problem Number	Problem—Active	Date of Onset	Problem—Resolved	Date Resolved
1	Psychophysiologic disorder			
	Headaches	1953		
	Retention of right supraorbital scar	1953		
	Dysmenorrhea	1943		
	Dysuria	1943		
2	Menorrhagia	1963	Two dilation and curettages	1966
			Two miscarriages	1964
			Two pregnancies with bleeding	
			Administration of Premarin and Provera	1970
3			Auto accident with head injury	1953
			Incomplete surgery to repair right supraorbital scar	1953
4	Depression, acute and chronic, with suicidal ideation and insomnia			
5	Borderline personality organization, hostile-dependent and narcissistic			
6	Nontoxic colloid goiter	1969		
7	Maternal history of menopausal menorrhagia with hysterectomy and postoperative depression			
8	Adverse drug reactions			
	Methysergide (Sansert): weight gain	1970		
9	History of drug abuse with seizures			
	Glutethimide (Doriden)	1970		
	Phenobarbital withdrawal seizure	1971		
	Tuinal	1971		
10			Dislocation of left shoulder	1969
11	Compression fracture: thoracic vertebrae 8, 9, 10 (possibly related to problems 3 and/or 9?)			

manipulativeness, 4) mild depression (possibly involutional), 5) mild anxiety, 6) mild insomnia.

Social: 1) hostile-dependent relationship with husband and parents, 2) disposition.

Organic: 1) menorrhagia, 2) rule out migraine, 3) various somatic complaints, 4) status after car accident with head and back trauma, resolved.

He used these divisions to help organize his thinking about the patient. He assessed each problem individually and developed a treatment plan. A sample progress note follows:

Progress Note—7/16/71

Social Problem 1: Hostile-dependent object relationships

Subjective: The patient states, "I love my husband and yet I am furious with him. He never wanted me to do anything. He treats me like chattel. His days have been far more stimulating than mine and I'm jealous. I'm angry, but I've never expressed it. I berate *myself.* I *need* to have my parents and my husband favor me to feel good."

Objective: The patient wanted to be a dancer but, "not having enough guts to pack up and leave" her father, who disapproved of her career choice, she continues to blame him for her unfulfilled life. The patient took an overdose of medication when Dr. X. refused to prescribe any more drugs. She has engaged a number of physicians in her gynecologic complaints, trying to obfuscate interhospital communication; she has escalated her demands for "cure" through more potent psychotropic medications and more radical surgery (hysterectomy).

Assessment: The patient feels entitled to the best of everything, yet is incapable of obtaining even a feeling of well-being on her own; she is therefore extremely dependent on significant objects. Possibly because of her mother's relative withdrawal, she sees men as the suppliers of good feeling. She has fused her libidinal and aggressive drives. As a result partly of her father's domineering personality and partly of her projected hostility, she sees men in sadistic roles and accepts a masochistic position. Her object relations are transitional at best. She expresses her conflicts (rage versus need) somatically in headaches and dysmenorrhea.

Plan: Begin insight-oriented psychotherapy three times a week as an outpatient. Expect hostile, dependent transference. Coordinate patient's medical program to ensure optimal communication of her masochistic and dependent style with physicians. The patient should not have gynecologic surgery unless absolutely necessary.

Several months later a consultant reviewed the case. His general approach differed somewhat in that he did not use "psychiatric, social, and organic" as categories, but rather simply listed all the problems this patient

TABLE 2
Flow Sheet of Medications for Patient C.M. (Case 2)

Date	Seizures	Anticonvulsant Medication*
1949–1959	Onset of minor motor seizures: surgical clipping of arteriovascular malformation	Unknown dosages of Dilantin and phenobarbital
1960		Dilantin discontinued; phenobarbital 100 mg.; Mysoline 750 mg.
1963	Seizure disorder controlled	Phenobarbital and Mysoline discontinued; Mesantoin dosage unknown
1966		Mesantoin 500 mg.
1970		Mesantoin 500 mg.
4/9/71		Mesantoin 500 mg.
5/12/71 (Hospital X)		Mesantoin 500 mg.
5/14/71 (Hospital X)	Possibly one tonic spell	Mesantoin 500 mg.
5/17/71		Mesantoin 500 mg.
5/18/71 (Admission to McLean Hospital)		Mesantoin 500 mg.
5/22/71	Right-sided tonic seizure with subsequent drowsiness	Mesantoin 500 mg.
5/23/71	Right-sided seizure with subsequent sleep	Mesantoin discontinued; Dilantin 500 mg.; phenobarbital 150 mg.
5/25/71		Dilantin 500 mg.; phenobarbital 150 mg.

*Dilantin = diphenylhydantoin, Mysoline = primidone, Mesantoin = mephenytoin.
**Librium = chlordiazepoxide, Elavil = amitriptyline, Tofranil = imipramine, Thorazine = chlorpromazine.

faced. The problem list that resulted was somewhat different and included several problems not listed by the admitting physician (see table 1).

Case 2. C.M., a 39-year-old married woman, was admitted with an acute psychotic episode. Her multiple problems included seizure disorders, arteriovascular malformation of the left parietal lobe, acute psychosis, and chronic depression in a narcissistic personality. In this case, in which the medical and psychiatric problems were interrelated, a flow sheet documenting certain objective parameters was extremely useful (see table 2; the material has been adapted somewhat for purposes of publication).[1]

DISCUSSION

The consultant in case 1 did not feel that it was necessary to have a format of psychiatric, behavioral, and social categories to guide his thinking. He felt that these divisions, as well as relevant demographic considerations, should be included in any problem list. The consultant's list also differed from the admitting physician's in that he noted additional problems, such as "drug abuse." The admitting physician was actually aware of this problem and responded to it, since he discontinued all medications during the initial period of evaluation. However, he did not document his awareness in the problem list or in the progress notes. Thus the utilization review committee or any other interested health care providers would not have ready access to the admitting physician's full analysis.

The consultant also tended to group the admitting doctor's problem categories under more sophisticated headings (i.e., psychophysiologic disorder, borderline personality organization). Accordingly, several problems could be defined so that they fit into a more meaningful rubric at a higher level of understanding. For example, after the consultant's visit, the admitting resident was able to group his associated psychiatric problems of infantile narcissism, seductiveness, manipulativeness, and mild anxiety (#1, 2, 3, 5) and the social problem of hostile-dependent relationships (#1) under the heading "borderline personality organization in a hysterical personality." This heading would then represent a new problem (e.g., psychiatric problem 7) in his problem list, which he would date as to the time defined. He would discontinue the other problems with the note "see psychiatric problem 7."

On the other hand, if one is unsure of the diagnosis, then the sign, symptoms, or laboratory value should be stated as the problem. For example, instead of "rule out migraine," the second organic problem should be "headache," with a note that suggests migraine and includes a detailed plan for working up the problem. In the same

manner, "rule out hallucinations" is not the problem when "looking around or intermittent staring" is what has been observed and is certain. As the evaluation of the problem proceeds, documented in the progress notes, this problem might become "visual hallucinations" and then "chronic schizophrenia, paranoid type."

Problems may thus be signs, symptoms, laboratory values, diagnoses, psychodynamic formulations, or social or economic difficulties. A problem may also be "incomplete data base" if the information defined as necessary is missing, thus making evaluation and/or treatment a "problem" for both therapist and patient. The same case history will be interpreted differently by mental health personnel with different orientations and differing levels of experience, e.g., psychoanalysts, medical students, behaviorists, social scientists, and psychologists. A behaviorally oriented consultant, for example, might develop a problem list for patient P.H. like that shown in table 3.

The value of the problem-oriented approach is that the physician must clearly specify (in the problem title and progress note) what his orientation is, how he assesses the data, what he tells the patient, and then what the results of his plans are. In this manner, treatment is documented, communication among mental health personnel is simplified, and research is stimulated.

The flow sheet for case 2 is presented to introduce this useful technique to psychiatry, where psychopharmacology is rapidly becoming more prominent. Since such a great number of drugs is now being prescribed, their side effects and interactions have become crucial in treatment. The flow sheet allows the physician to quickly note and evaluate the usefulness of all the patient's previous, as well as present, medications.

Several difficulties in applying the problem-oriented approach to the psychiatric record are apparent. The psychodynamic formulation may be sufficiently complicated that crystallization into a diagnosis or phrase is difficult or meaningless. In that case, one must then write "Problem 1, see formulation"; but it is quite possible that as time passes one will be able to state the essence of the problem more succinctly. That the state of the art is imprecise does not argue against use of the method.

Secondly, the philosophy of viewing the patient as a list of *problems* is to some discouraging, and seems to ignore the patient's strengths and adaptive solutions. However, the patient comes to the doctor because he *is* symptomatic and seeks consultation and treatment for his complaints. How the physician integrates therapeutic modalities to amplify the patient's own strengths is an important component of the "assessment" and "plan" portions of the progress notes.

Similarly, it is said that to "fragment" an individual into various problems is to ignore his basic individuality and wholeness. However, the more complete the problem list, the closer it approximates the patient's individuality;

TABLE 3
Behaviorally Oriented Problem List for Patient P.H. (Case 1)

Active Problems	Inactive Problems
1. Suicidal behavior	
2. Drug dependence: Barbiturates and glutethimide	
3. Headaches	
4. Depressed behaviors: Feels unhappy; Multiple somatic complaints; Critical of husband; Fears of abandonment	
5. Incomplete data base	
	6. Menorrhagia: Estrogen abnormality
7. Marital dysfunction	

and each problem is assessed and treated *in the context* of the other problems. Just as in medicine one does not treat congestive heart failure in the presence of renal impairment as one treats it in a patient with adequate kidney function, so one cannot treat depression out of context, as in case 1, by not taking into account this patient's menorrhagia and her maternal history of severe depression following hysterectomy.

Finally, it might be argued that at least in analytically oriented psychiatry, as in no other field of medicine, the *patient* is the record. Whereas in medicine a patient need not have any expertise in cardiology for his congestive heart failure to respond to digoxin, in psychiatry "working through" a problem to a change in behavior or feeling means that the patient has gained insight and shared his doctor's expertise in examining his psychological makeup. Indeed, the therapeutic sessions are a series of "progress notes." There can be no quarrel with the patient's being the ultimate record of psychotherapy, but the advantages of an accurate, *written* record are substantial: quick information retrieval, documentation of effective treatment programs, research, teaching, and various administrative uses.

The problem-oriented record faces many difficulties in psychiatry in that it puts pressure on the complicated dynamic record. The "pneumococcus," so to speak, has not been isolated in schizophrenia. Nevertheless, in the most general sense, what this approach offers is a scientific attempt to find out what we are doing.

APPENDIX 1

An Outline of the Four Basic Sections of the Problem-Oriented Medical Record

DATA BASE

Chief Complaint
Present illness
Psychosocial history
Family history
Physical examination, past medical history, review of systems
Mental status examination
Psychological testing
Laboratory studies

PROBLEM LIST

Problems (to be stated at the physician's level of understanding):
- Etiologic, diagnostic, dynamic (e.g., schizophrenia)
- Abnormal laboratory findings (abnormal EEG)
- Physiologic (intention tremor)
- Social, demographic (separated from spouse)
- Behavioral (temper tantrums)
- Mental status (thought disorder, hallucinations)
- Symptoms (insomnia)

The problems are numbered and the number is constant throughout the record; the list of problems becomes an index to the patient's record.

PLANS

Specific statements of:
1. The protocol for "working up" each problem, the differential diagnosis, exactly what additional information is needed, how it is to be obtained, and in what order
2. The treatment (e.g., psychotherapy, behavior therapy, ECT, psychopharmacology); what parameters are necessary to judge efficacy
3. What the patient is to be told

FOLLOW-UP

Progress notes (numbered and titled; organized into subjective or symptomatic data, objective data, assessment, and plans)
Flow sheets (where applicable)

Follow-Up on Baxstrom Patients Returned to Hospitals for the Criminally Insane

BY HENRY J. STEADMAN, PH.D.

Of 967 patients transferred from hospitals for the criminally insane to civil mental hospitals as a result of the Supreme Court decision in the Baxstrom case, 26 were returned to hospitals for the criminally insane between 1966 and 1970. There was no factor or set of factors that significantly differentiated this group from other Baxstrom patients, although the 26 tended to be younger and to have more serious criminal records. Some differences were also found between patients returned via civil proceedings and those returned via criminal proceedings.

IN OUR PREVIOUS discussions of the 967 Baxstrom[1] patients (2–4), we noted that only 26 (2.7 percent) of them were returned to Matteawan or Dannemora, New York State's two hospitals for the criminally insane, at any time after their original transfers in 1966. Until recently there were no data available on these returnees with which to answer the questions that have been raised about this group, including how it may have differed from the rest of the Baxstrom patients. Our intent here is threefold: to briefly describe the returnees, showing that they differed very little from the rest of the Baxstrom patients; to report some differences among the returnees; and to discuss the types of behaviors that led to their returns.

The first point that must be emphasized when talking about the Baxstrom returnees is that they comprise a very small part of the Baxstrom population. It is very easy when looking at the serious problems these patients present to generalize the problems to all the Baxstrom patients. This should not be done. As already noted, the returnees comprise only 2.7 percent of the entire population. Also noteworthy is that one-third of the Baxstrom patients were in the community four and a half years after their transfers; their cumulated release rate was higher than that of all adult, chronic, civilly committed patients. With this note of caution, let us look at the characteristics of the returnees.

The most striking feature of the Baxstrom returnees is that their backgrounds differ little from the other Baxstrom patients. About the same proportion of returnees as other Baxstrom patients came from Matteawan and Dannemora (50 percent of the returnees came from Matteawan whereas 59 percent of all the Baxstrom patients were from Matteawan). The racial proportions were also about the same in the two groups: a ratio of 58 blacks to 42 nonblacks for the returnees compared to a 50:50 ratio for the other Baxstrom patients. Minimal differences were also found in the number of previous arrests, the number of previous incarcerations, the number and type of violent crime convictions, and the number and type of sex crime convictions.

We were able to find only two factors differentiating the Baxstrom returnees from the other Baxstrom patients. The returnees were much younger than the other Baxstroms: the average age of returnees at the time of transfer was 33, while the average of the other Baxstrom patients was 47 at the time of transfer. The second differentiating factor was the returnees' Legal Dangerousness Scale scores. (This scale and its use as a summary measure for the criminal history of the Baxstrom patients before institutionalization are described in detail elsewhere [5].) The score can range from 0 to 15. The higher the score, the more serious the criminal history. The average score for the male returnee was 9.2 and for the other Baxstrom males was 6.0 ($t = 3.287$, $p = .01$).[2] This difference does not mean, however, that the return could have been predicted from the scores. Over 90 percent of the Baxstrom patients with a score of 9 or more did *not* return to Matteawan or Dannemora. It does mean that the younger patients with more serious criminal histories were the group most likely to return, but the vast majority even of this highest risk group did not return.

[1] The Supreme Court held (1) that Johnnie K. Baxstrom had been denied equal protection of the laws by the statutory procedure under which he was held at Dannemora State Hospital for prisoners declared mentally ill while serving a criminal sentence. When his maximum sentence expired in 1961, Baxstrom was civilly committed to Dannemora under the provisions of Section 384 of the Correction Law, which gave procedures for retaining persons found to be still mentally ill on expiration of their sentences. The Supreme Court in effect held Section 384 to be in violation of the equal protection clause of the Fourteenth Amendment. The nearly 1,000 patients affected by the decision were transferred from New York State's two hospitals for the criminally insane to civil mental hospitals.

[2] The number of female returnees, two, was too small to allow a comparable testing of their scores.

TABLE 1
Behavior Leading to Return of Baxstrom Patients Under Section 85 (N=15)

Behavior	Number	Percent
Threats only	4	26.6
Assaults against property	1	6.7
Assaults against persons		
With no injury or minor injury	4	26.6
With major injury	1	6.7
Resulting in death	1	6.7
Other (e.g., wife's request, criminal history)	4	26.6

REASONS FOR RETURN

The 26 Baxstrom returnees separate into two very distinct groups based on the path of their return.

The first group of 15 were returned to Matteawan under Section 85 of the New York State Mental Hygiene Law as "dangerously mentally ill." This is a civil procedure. These patients were returned because of behavior in the hospital defined as dangerous to the staff, to other patients, or to the community if the patients were to escape. These 15 patients had a wide range of behaviors causing their return (see table 1). For the six returnees with assaults against persons, there was a single serious incident that precipitated the return. For the four with threatening behavior only and for the one patient with assaults against property, there was a series of incidents culminating in the return to Matteawan.

The remaining four patients who returned under Section 85 (classified as "Other" in table 1) did nothing after their transfers to civil hospitals that specifically led to their return. One was described in a letter requesting Section 85 proceedings as "the most violent and dangerous patient in Dannemora State Hospital" before his transfer. However, during his five weeks in the civil hospital before being returned under Section 85, there was no report of any incident while he was kept in maximum security with a special security attendant assigned to him 24 hours a day. The records of the other three patients offered only vague reasons for their return. One patient, who was transferred under a "forthwith" Section 85 order after one day in a civil hospital, had his order rescinded three weeks later when his hearing took place. Another patient was sent to Matteawan apparently because his wife read in the newspaper about "Operation Baxstrom" and wrote the hospital director that she was afraid her husband would escape and harm her, although the patient had given no indication of dangerous behavior after his transfer. The last patient in the "Other" category was returned, according to hospital records, because of his criminal history *before* his Baxstrom detainment; there were no reported behavioral problems after his initial transfer.

The second group, consisting of 11 returnees, had been released into the community at some time after their original transfer to a civil hospital but were rearrested. Six of the 11 were found incompetent to stand trial after their arrest and were returned to Matteawan. The other five were convicted, incarcerated, and then transferred to Dannemora as psychiatrically disordered criminals. The charges and institutionalizations leading to the return of these 11 patients are shown in table 2.

With the exception of one unspecified parole violation, all the charges for which these patients were returned were felonies. In addition, the men had an average of one other previous arrest between their release and the current charge. The average length of stay in the community for both this group and the four Section 85 patients who were in the community for some time was 12 months. In no instance did any of the 11 in the criminal group return to the community after returning to Matteawan or Dannemora. The parole violator completed his time and was transferred to a civil hospital, where he remained at the end of our follow-up.

Just as younger age and more serious criminal histories differentiated the Baxstrom returnees from the other Baxstrom patients, these factors differentiated the Section 85 returnees from the criminal procedure returnees. At the time of transfer, the average age of the entire Baxstrom population was 47. The average age of the Section 85 returnees was 35, and of the criminal returnees, 30. The average Legal Dangerousness Scale score for all the Baxstrom patients was 6.0; for the Section 85 returnees it was 8.1; for the criminal returnees it was 10.4. A third factor distinguishing the Section 85 from the criminal procedure group was the number of previous arrests. The average number for the Section 85 group was 3.5 (lower then that for all the Baxstrom males, which was 4.3); the criminal procedure returnees averaged 5.1 previous arrests.

DISCUSSION

The Baxstrom patients who were returned to Matteawan and Dannemora after their original transfers were for the most part acting out in very violent ways. However, this group of 26 represented only 2.7 percent of the 967 patients transferred. The vast majority of the Baxstrom patients were suitable for care in civil hospitals and one-third of all the transfers were in the community four and a half years after their transfers. While the patients discussed here had serious criminal charges and convictions after their return to the community, only 17 percent of all Baxstrom patients released into the community were rearrested, most often for violations or misdemeanors. Unfortunately, we were able to find no factor or set of factors that could have selected these returnees from all the Baxstrom patients without a very large number of false positives—i.e., patients with the same characteristics who did not act out violently.

Section 85 of the New York State Mental Hygiene Law, under which 15 of the 26 returnees were returned, is primarily retrospective in character. It defines someone as "dangerously mentally ill" if he committed an act

TABLE 2
Incident Precipitating Return of Baxstrom Patients Through Criminal Procedures (N=11)

Charge	Procedures and Institutionalizations Leading to Return*
Second-degree assault and possession of a dangerous weapon	Ten-year sentence, prison, Dannemora
Third-degree burglary and unlawful use of a motor vehicle	Five-year sentence, prison, Dannemora
Second-degree manslaughter	Three- to six-year sentence, prison, Dannemora, prison
Second-degree larceny	Five-year sentence, prison, Dannemora
Parole violation	Prison, Dannemora, civil mental hospital
Second-degree robbery	Incompetent, Matteawan
Burglary	Incompetent, Matteawan
Attempted second-degree robbery	Incompetent, Matteawan
Second-degree robbery	Incompetent, Matteawan
Attempted first-degree robbery	Incompetent, Matteawan, court, four-year sentence for first-degree robbery
Homicide, grand larceny, and burglary	Incompetent, Matteawan (malingerer), court, ten- to 20-year sentence for first-degree manslaughter

*The last notation in each history indicates the patient's location at the end of the follow-up period.

that, if it occurred in the community, would have been classed as a felony. Although the interpretations of this section in the cases of some of the Baxstrom returnees may have stretched this definition, it does provide a fairly firm basis for court action.

In the criminal proceedings under which the other 11 Baxstrom returnees were returned, the judicial determinations that returned them involved mainly an assessment of current mental states. Once indicted and found incompetent to stand trial they were sent to Matteawan, or if they were first convicted and then displayed disordered behavior they were sent to Dannemora through an administrative action. The New York State Criminal Procedure Law that became effective on September 1, 1971, is less straightforward, dividing the incapacitated defendants into "dangerous" and "nondangerous" groups. In the case of the indicted incapacitated felony defendant, two psychiatrists must make a recommendation to the court regarding dangerousness that includes a prediction of probable future behavior. While the ultimate decision is the court's, during the first four months there was 90 percent agreement between the courts and psychiatric reports. Thus, the type of problem we have discussed here about selecting out the Baxstrom returnees from the Baxstrom patients who made much better adjustments has become even more important.

The Writ Writer

BY MICHAEL F. CLEARY, M.D.

The author discusses patient-prisoners on forensic psychiatry units who seek to improve their situation by contacting the courts by means of writs. This practice is becoming increasingly evident as more attention is focused on the rights of prisoners and prisoner-patients. Patients who are skillful in this area may not only improve their legal situations, but may also acquire added prestige among fellow patients.

THE PATIENT ON A FORENSIC PSYCHIATRY unit has two immediate problems—his mental illness and his current conflict with legal authority. A third problem, compounding and initially related to the first two, is his lack of financial resources. As a consequence, the vast majority of patients in such units cannot afford a private at-

Dr. Cleary is Chief of the Maximum Security Division, Arizona State Hospital, 2500 E. Van Buren St., Phoenix, Ariz. 85008.

torney; a public defender may be assigned to a patient's case or a court-appointed attorney will act as defense counsel. The public defender may have a large case load and only a limited amount of time to devote to each client; he may be inexperienced, and he may not inspire the confidence that a private or "street" lawyer does.

The court-appointed lawyer may have excellent qualifications and may be capable of doing a thorough defense job, but the patient may not trust him since he is court-appointed and therefore represents the system with which the patient finds himself in conflict. A further limitation of the attorney's role in the eyes of the patient is that his activity may be related only to the offense with which the patient is charged, whereas the patient may wish to air a number of different issues in court.

WHY PATIENTS WRITE WRITS

The patient often comes to the forensic unit with a background of repeated conflicts, misunderstandings, and losing encounters in both criminal and civil proceedings. He may have experienced many aspects of the law—child custody hearings, divorce court, bankruptcy proceedings, garnishment of wages, traffic summonses, civil suits for damages, and so on. The cumulative effect of all of this may have been to crystallize certain attitudes in the patient, for example, a distrust of and cynicism about the system, leading to a lack of acceptance of court decisions or of attorneys' advice. The more aggressive and self-confident individual might resolve to challenge and, if possible, to overturn the disposition of his case. To accomplish this he initiates legal moves of his own, usually in the form of writs addressed directly to the courts—sometimes to the original court that sentenced him but more often to state courts of appeal or to federal courts. A patient or prisoner may have several appeals in motion simultaneously. The conscious motivation for this behavior may be expressed as a device to cut through red tape, to circumvent, to eliminate lengthy delays, or to point out omissions or mistakes. On a deeper level it may represent the expression of omnipotent fantasies, the idea that oppressive external forces can be routed by a stroke of the pen.

The magic is not only in the written communication itself but also in the arcane, stylized phraseology so peculiar to legal documents. The inmate who can become familiar with legal processes and who can truly understand not only court proceedings but also the mechanism of the law that can modify, relieve, or aggravate his situation may earn prestige and respect from fellow inmates and may be called upon to initiate legal proceedings for them. His advice may be sought and his legalistic talk received with deference by fellow inmates and even by the staff. Since the majority of prisoners and patients on forensic psychiatry units lack a formal education (a survey in Arizona State Prison in 1971 showed that only three percent of the inmates had received a high school diploma), a man who can read law books, understand the content of court orders, and write a reasonable facsimile of what appears in a legal document can quickly gain impressive stature.

REDRESSING GRIEVANCES

It is hardly surprising that many of the nation's 300,000 prisoners are discontented with their lot and would like to achieve changes faster than society is ready or willing to grant them. Recent changes affecting the rights of prisoners at the time of arrest or at any subsequent time have focused attention on the many possibilities of procedural and judicial error in the handling and disposition of the offender, whether he is mentally ill or not.

If the minutely prescribed rules are not followed to the letter throughout the entire process of arrest, trial, and sentencing, the prisoner-inmate has the option of moving to reverse a decision based on an error if he feels that his situation will be improved by so doing. Not only might his freedom hang in the balance, but the possibility of monetary indemnification may also be pursued as an additional prize.

Every day, decisions are reversed and appeals are successful as the courts strive to refine the administration of the law and to ensure constitutional guarantees. Thus, a constant flow of encouraging news may be noted and absorbed by whoever tries to beat the system. The prisons, the philosophy of confinement, and the concept of punishment have all been questioned, reexamined, and attacked to such a degree that confinement or involuntary commitment may seem intrinsically wrong to the inmate, especially to one who agrees with the criticism but who is not interested in constructive alternatives. Therefore, there is incentive, encouragement, and opportunity to do something about one's situation, and to some prison inmates the existing framework of the courts seems to be the most ideal vehicle for such efforts.

The courts may be used to redress grievances associated with the inmate's current status and living conditions, as well as those relating to his legal disposition. He may complain about the handling of his mail, access to visitors, food, attention to medical complaints, assaults on his person by other inmates or by staff members, deprivation of any aspect of his civil rights, absence of recreation, or any feature of institutional life that does not appeal to him.

Complaints may be based on delusional beliefs and may involve political or other public figures. The writer of writs may pursue only one issue, carrying his brooding resentment over one theme as his major preoccupation for months or years; or he may jump from one issue to another, taking up the cudgel for others when he tires of his own problems. He may collaborate with his attorney or only render lip service to him, feeling that his own ideas and strategies are more subtle and farseeing. Often the patient will express dissatisfaction with the lawyer, announce that he is about to fire him, and request the court to appoint another one. The process may be repeated, with one patient going through several changes of

attorney in the course of litigation. Here, the inference is strong that the patient has his own ideas as to how his case should be conducted, and professional advice may be suspect.

The use of law books and journals may be requested; recent court decisions have affirmed prisoners' rights to have an extensive law library made available for their use in preparing legal documents and as resources in researching remedies available to them. These decisions reflect a growing awareness of the inmate's sensitivity to his rights and privileges. Many inmates will keep a file of briefs, examination reports, copies of correspondence, court orders, and other case-related material. This may be carefully stored out of sight or ostentatiously worked on in a conspicuous location. Attention to spelling, punctuation, and sentence construction signifies the inmate's desire not to be regarded as naïve or ignorant. Acknowledgment by the court of his letter indicates that he has made an appropriate contact and encourages further effort.

No single diagnostic category of mental illness is identifiable as being most likely to produce the writ writer. Sociopathy is clearly a prevalent condition on a forensic psychiatry unit but is by no means applicable to all patients. The writer who harps on one theme for years, refusing to accept the judgment of any court and generalizing his complaint to society at large, is more likely to be a paranoid personality, if not schizophrenic. The patient who writes with a sense of urgency in response to an immediate situation may be the victim of an acute anxiety attack. A few patients may not have any mental disorder or be particularly sociopathic, but rather, may be inappropriately placed and pursue their legal rights in a persistent and reasoned manner.

A number of such patients have been seen on the Forensic Psychiatry Unit of the Arizona State Hospital during the past two years; some of these cases are presented here. All but one have served or are serving terms in the Arizona State Prison. None of these men is considered psychotic. The other patient, who is psychotic, has been hospitalized continuously since 1964.

CASE REPORTS

Case 1. This 49-year-old man was committed to the hospital in 1964 on the grounds that he was unable to assist in his own defense, the court specifying that he should remain in the hospital until he was found competent to stand trial. He had been charged with murder in the shooting of his seven-month-old daughter. His resentment of his commitment, which he described as "railroading," was compounded by the court's finding him incompetent and appointing a guardian to take care of his estate.

The patient had been diagnosed as a paranoid schizophrenic. His letters to the courts have had regard to alleged violations of constitutional rights and evoked responses from the judge of the federal district court and the presiding judge of the county superior court, both of whom expressed concern at the amount of mail directed to them and advised the patient that the federal courts could not act until all possible remedies through the state courts had been exhausted. The patient told staff members that he would force the psychiatrist to release him because of the writs he had filed. He alleged that his hospitalization was a political plot and made an escape gesture to "force the hospital into a showdown." He was obsessively concerned with following regulations the "right" way and with forcing a rigid interpretation of ward management policies on other patients.

Prognosis for this patient is poor, and his writs reflect a lack of flexibility in thinking, a persistent hostility and mistrust, and a sustained persecutory trend. In this instance the writ communicates in a tangible form the patient's expressed belief that his commitment results from an elaborate conspiracy; putting his statements on paper gives him a permanent record to refer to so that he can exclude the possibility of being misquoted and so that he will be less likely to contradict himself.

Case 2. This 26-year-old unmarried man was readmitted to the hospital in December 1971, having been charged with aggravated assault on a deputy in the local jail. He had been confined to the jail since his earlier discharge from the hospital nine months previously. This patient had a long history of confinement in jails, prisons, and forensic psychiatry units in several different states. He stated that during his recent confinement in jail, the personnel had trampled on his rights by taking his dictionary and legal papers from him. He stated that he had incurred the enmity of the deputies by preparing writs for other inmates, resulting in the freeing of several of them.

In addition to facing the charge of aggravated assault, the patient is appealing a conviction for armed robbery for which he had been sentenced to a long term of imprisonment. The patient perceived a number of legal errors and what he considered to be injustices in his case; for example, the probation report prepared prior to his sentencing had referred to a charge of sodomy, which the patient explained as having allegedly taken place when he was nine years old and as amounting to no more than sex play between children. During his hospitalization, he became involved in a number of other activities such as knitting sweaters to sell and crocheting. These activities were a little incongruous in a muscular, athletic-looking, and occasionally aggressive young man. They were explained on the basis of his need to have funds to pay for his legal expenses, including the cost of paper, typing, notarizing, and mailing. The patient was particularly sensitive to what he perceived as any misuse of authority and expressed himself forcibly and bluntly when he felt the occasion called for it.

The patient had prepared a writ addressed to the United States Court of Appeals for the Ninth Circuit in the form of a motion for appointment of counsel to represent his appeal cause. On admission in 1971, the patient was found to be without a mental disorder and was again returned to court for the disposition of charges. Although his formal education had not progressed beyond the fourth-grade level, this patient was highly skilled in presenting his case to the courts, in researching legal documents, and in retaining detailed information about his previous experiences in court.

Case 3. This 31-year-old unmarried man was transferred to the hospital from the state prison for evaluation and treatment. He had spent 11 years in the prison, having been convicted at the age of 20 of first-degree murder. Recently while in the prison he had developed an acute anxiety attack in response to racial tension in general and, specifically, to sexual assaults by one racial group on a number of younger patients. The patient responded to this by exaggerating the extent of the situation and by addressing numerous letters to state officials, including the Governor of Arizona, the chairman of the parole board, and the

governor of his own state in the South. He prepared a lengthy writ for transmission to the United States District Court in which he referred to earlier certified letters he had addressed to the governor and to the Department of Corrections. On admission to the hospital, he focused his conversation on the situation in the prison that had led to his civil commitment and that he sought to have exposed as a major scandal by having it aired in federal court.

This patient has spent much of his time in prison reading and studying law books and had been the author of several writs in the past. Since he came from a southern state, he felt that, naturally and instinctively, he would rebel against many of the practices and policies at the prison and that his philosophy would not be acceptable to prison authorities. To get around this situation he used the threat of court action to correct or influence situations that were not to his liking.

The patient's transfer from prison was soon followed by a more flexible approach to racial and social situations. The writ writing diminished; he became aware of his tendency to try to intimidate people by this maneuver and withdrew several letters and writs that he had prepared. In this instance the writ was used as a defense against an intolerable and sometimes overwhelming situation. The patient has been employed in the mailroom in the prison, and his quasi-clerical status has given him some additional prestige.

CONCLUSIONS

The writ writer is most likely to be seen on the forensic psychiatry unit of a state hospital. He is very often indigent, has a limited formal education, and is of average or better than average intelligence. In two of the three cases cited the patients' diagnosis was antisocial personality. The absence of psychotic illness in these two patients resulted in a greater degree of flexibility and imagination in their coping with problems arising out of conflict with the law; this contrasts with the schizophrenic patient, who obsessively focused his attention on one area of alleged injustice or unfairness.

Patients who habitually write writs have a need to use legal books and dictionaries, constantly endeavor to broaden their vocabulary, and tend to confide in an attorney rather than in a psychiatrist. The psychiatrist on the forensic unit is often approached with some suspicion since he is perceived as a state employee, as being part of the state establishment, and as a challenge to the patient's assumed state of illness.

Writing writs is part of the overall communications process a patient engages in; letters to attorneys, relatives, and friends and notes to psychiatrists and other treating personnel are other aspects of this communications effort. In the case of a patient of average or better than average intelligence who has been frustrated and limited by poor educational opportunities, the formal language of legal documents affords him a structure and workable tool in his effort to modify an adverse situation. The threat of legal action may also be used as a deterrent from abuse or from disregard of the patient-inmates' privileges in prison, jail, or the hospital. As increasing awareness of legal complexities is thrust upon the public—including offenders, patients, hospital staff, and attorneys—more writs will be written, more communications initiated, and more short-circuiting contacts made.

The Attitudes of Patients and Aides Toward the Role of the Psychiatric Aide

BY LEONARD HANDLER, PH.D., AND GERALD PERLMAN, PH.D.

It has been difficult to evolve a system whereby psychiatric aides can be effectively selected and oriented to their roles. In an attempt to involve the patient in an evaluation of the aide's role, the authors interviewed 80 patients as well as 40 aides. Regarding the aide's function, patients were significantly more concerned than aides with humanistic, as opposed to custodial, values. "Humanistic" aides were evaluated significantly more favorably by patients than were "custodial" aides.

NEUROPSYCHIATRIC HOSPITALS have typically employed poorly educated and/or emotionally unstable individuals as psychiatric aides. Yet the aide is with the patient for a longer period of time than any other hospital employee, and he therefore plays a crucial role in patient treatment. In many cases, interaction with the aide is the only contact a patient has with any staff member for long periods of time. One major problem in this area has been to evolve a system whereby aides can be selected more effectively.

Dr. Handler is Professor of Psychology, University of Tennessee, 1303 W. Cumberland Ave., Knoxville, Tenn. 37916; Dr. Perlman is Clinical Psychologist, Eastern State Psychiatric Hospital, Knoxville, Tenn.

The authors wish to thank the staff and patients at Eastern State Psychiatric Hospital who participated in this study.

A great deal of research has been done in an effort to determine the personal qualities of the "good" aide. However, early studies seemed to emphasize efficiency, as determined by personnel ratings by superiors (1–3); little effort was made to define what supervisory personnel meant by "good" or "poor" adjustment. Thus the more satisfactory aide was probably one who was on time, was seldom absent, and who caused no trouble. This approach is totally lacking in any broad conception of the meaningfulness of patient-aide interaction.

The criterion problem has been emphasized by Yerbury, Holzberg, and Alessi (4), Schmidt and Cohen (5), and by Tarjan, Shotwell, and Dingman (6). The latter authors found that nursing supervisors felt conservatism, passivity, and introversion were the best signs of a good aide, while professional staff felt that the better aide was more outgoing and opinionated. Hamister (7), in what appears to be the first attempt to include patients' judgments as a criterion for evaluating aides, attempted to determine whether there was agreement among doctors, nurses, and patients as to the effectiveness of aides. Patients were more concerned with kindness and approachability, while the staff was concerned with the smooth running of the ward. However, while the staff was asked about the effectiveness of aides, the patients were merely asked to choose between best- and least-liked aides, in various comparisons. Thus the two groups were actually asked different questions. The best-liked aide is not necessarily the most efficient.

We believe that if the aide is considered to be an integral part of the healing situation, one of the most important judges of his success must of necessity be the patients with whom he interacts. Therefore this study was designed to follow the leads suggested in previous research, while attempting to reflect the views of both aides *and* patients. The following hypotheses were generated:

1. There will be a significant difference between patients' and aides' attitudes toward the role of the aide, with patients more concerned with humanistic as opposed to custodial values, and conversely, aides more concerned with custodial values.
2. Aides with a more humanistic approach will be more highly evaluated by patients and, conversely, those with a more custodial approach will be less highly regarded by patients.

METHOD

The data were collected at a large state mental hospital in Tennessee. The variables examined included sex, open versus closed ward placement, and length of hospitalization. Long-term hospitalization was considered to be any period over six months. Ten patients were questioned in each of the following eight cells: open-ward, long-term men; open-ward, long-term women; closed-ward, long-term men; closed-ward, long-term women; open-ward, short-term men; open-ward, short-term women; closed-ward, short-term men; and closed-ward, short-term women.

Aides were questioned according to the cell breakdown used for patients, thus including aides working in open and closed wards, with long- and short-term hospitalized patients, and with men and women. Representatives of both the day and evening shifts were used. Within each cell, three day aides and two night aides were questioned, comprising a total of five for each cell and a grand total of 40 aides, 20 men and 20 women.

The Custodial-Humanistic (C-H) Scale

In a pilot study, a random sample of patients and aides were interviewed concerning what each felt the functions of the aide should be. From these results a 15-item rating scale was devised that consisted of statements regarding various ward functions. Each statement was scaled 1 to 4, from "extremely important" to "not at all important." Prior to administration of the scale, cutoff scores were devised.

The Evaluation (E) Scale

For the patients' evaluations of the aides, a patient rating scale was used, consisting of 11 questions regarding actual behavior of the aide in question (8). Cutoff points were determined prior to administration of the scale.

Procedure

Patients and aides were approached and told the following: "We are doing a study to see how patients and aides feel about the role of the aide on the ward. We would appreciate your giving your opinion about the following statements. No names are being taken, so please feel free to answer truthfully."

The C-H Scale consisted of the following 15 items:

The aide should always obey the rules of the ward.

The aide makes sure the patients receive their medicine.

The aide must never lose his temper in front of patients.

The aide is willing to talk to patients on a personal basis.

The aide sees that the ward is kept quiet at all times.

The aide gives patients the chance to do things on their own.

The aide should never let the patient know he has made a mistake in working with the patient.

The aide treats patients as his equal.

The aide gets to work right on time.

The aide sometimes gives patients cigarettes or other treats.

If a patient breaks any rules at all, he should be punished.

The aide should be understanding of the patient's individual problems.

The aide sees that the patients do not get into fights on the ward.

The aide should sometimes put his own work aside to talk to patients.

The aide treats all patients the same.

The scales were verbally administered. For each ward used, aides were approached individually and were given

the C-H Scale. Then the same scale was individually administered to the patient. After he had completed the initial scale, each aide was pointed out to the patient, who then responded to items on the second scale concerning his feelings about the particular aide in question. The procedure was conducted on eight wards, and a total of 80 patients and 40 aides were utilized. Thus each aide received five patient evaluations, with one-half of the patients rating three aides and the other half rating two aides. Patients and aides were classified as either low, medium, or high based on each of the two scales. The mean of the five patient evaluations for each aide was then obtained, and each aide was placed in a low, medium, or high group for the 11-item E Scale.

RESULTS

A three-way analysis of variance was computed for the patient versus aide, open versus closed ward, and long- versus short-term hospitalization variables for the C-H Scale results. Patients were significantly more humanistic in their attitudes than the aides were ($F = 75.8$, $p < .001$). There was no significant difference between the scores of open- and closed-ward subjects (both patients and aides). Patients and aides involved with short-term hospitalization were significantly more humanistic in their attitudes than were those involved in long-term hospitalization ($F = 3.93$, $.05 > p > .025$). There were no significant interactions among the three variables. Thus patients were more humanistic than aides, whether they were in open or closed wards and whether they were short- or long-term hospitalized patients. Patients and aides involved in short-term hospitalization were more humanistic than those involved in long-term hospitalization, whether they were in open or closed wards. The results therefore support our first hypothesis.

To determine whether these results were due to differences in age and/or education for the patients and the aides in the various subgroups studied, the mean ages and mean years of education were calculated for each subgroup. The mean age for the aides was 38.7 years and for the patients, 40.3 years. The mean ages for long- and short-term hospitalization subjects were 40.7 and 38.9 years, respectively. Both of these differences are nonsignificant. Similar findings were obtained for level of education. Aides and patients had an average of 8.06 years and 8.03 years of education, respectively; the educational levels for long- and short-term hospitalization subjects were 8.3 years and 8.6 years, respectively. Thus the significant differences in degree of humanism between patients and aides and between long- and short-term hospitalization subjects are not artifacts of differences in age or level of education.

Chi-square analysis was employed to determine whether there were any sex differences in the degree of humanism expressed in the questionnaire. A nonsignificant chi-square value ($\chi^2 = .44$) was obtained for the patient data, and a chi-square value of 5.50 ($.10 > p > .05$) was obtained for the aide data. Thus there is a suggestion that female aides are more humanistic in their conception of their ward functions than are male aides.

The age of the patient was not a significant factor in his humanistic view. A chi-square value of 4.44 ($.20 > p > .10$) was obtained for younger patients (under age 35) versus older patients. When the age of the aides is considered, the results indicate that younger aides (age 35 or under) are significantly more humanistic in their orientation than those over 35 ($\chi^2 = 14.3$, $p < .01$).

The better-educated patients (ninth-grade education or higher) had a significantly greater humanistic outlook than did less well-educated patients ($\chi^2 = 8.60$, $p < .02$). The results were not significant for aides with regard to education ($\chi^2 = 3.89$, $.20 > p > .10$).

A chi-square analysis was employed to determine the relationship between the degree of the aide's humanism and the patient's evaluation. Those aides with a more humanistic viewpoint toward their role were evaluated significantly more favorably by patients, and conversely, those aides with custodial viewpoints were less favorably regarded ($\chi^2 = 21.09$, $p < .01$). These results confirm our second hypothesis.

The age of the aides was found to be an important factor in their evaluation by patients. Younger aides were rated significantly more favorably than their older colleagues ($\chi^2 = 9.06$, $p. < .02$). This finding is to be anticipated in light of the fact that younger aides were found to be significantly more humanistic in outlook. There was no significant difference between aides' sex or level of education and their evaluation by patients ($\chi^2 = .406$ and 1.97, respectively).

DISCUSSION

The hypothesis that patients would be significantly more humanistic than aides regarding their concept of the aides' function was confirmed. Aides were significantly more custodial in their outlook across all wards sampled. Patients and aides had different views of what the aide should do on the ward. The patient was concerned about being treated with consideration, while the aide was most concerned with keeping order and obeying the rules.

The nonsignificant findings for the closed ward-open ward variable could be due to the rotation of aides on the various wards; an aide does not necessarily work on one ward for a long period of time. Therefore his concept of the aide's role in the hospital is based upon his total hospital experience.

Short-term patients and their aides were more humanistic than long-term patients and aides. The longer the patients and aides stay in the hospital, the more custodial their concept of the aide's role becomes. This may be due to the effect of hospital routine on the patient and aide; the longer they are there, apparently, the less they expect or give in the way of decent treatment.

These data suggest that employment per se could change the aide's outlook from what it had been when he started his job. Thus, while he may have had a humanistic

outlook when he was first employed, his steady interaction with patients and the hospital structure might combine to gradually alter his viewpoint to that of custodian. Age is essentially unimportant; length of employment is the relevant factor. When patients evaluated aides, they evaluated younger aides more favorably than those who were older. Again, this can be explained as an artifact of length of employment and the development of a custodial viewpoint.

The findings of this study underline the importance of carefully reviewing and reevaluating ward procedures and policies in the neuropsychiatric setting. The gross differences in patient and aide expectancy can hardly make for an effective treatment program. Although always subject to a certain amount of interpretation by staff, hospital policy is usually dictated by the administrative personnel. While joint policy-making meetings between patients and aides might be helpful, we feel that ward procedures will change only if administrative personnel are brought into the picture and are involved in attempts to produce effective treatment programs. Changes in ward procedures and in the attitudes of personnel and patients will be brought about only if the entire patient care delivery *system* is understood by all those employed within it.

IN MEMORIAM

Bernard Glueck, Sr.
1884–1972

A MAN OF UNUSUALLY BROAD INTERESTS, Dr. Bernard Glueck will long be remembered for his uncanny intuition for innovations that made lasting contributions to psychiatric history. After a long and illustrious career in his chosen profession, Dr. Glueck died October 5, 1972, at his home in Butner, N.C., at the age of 88.

Born in Poland in 1884, he came to America in 1900. He went first to Chicago and then lived for a short time in Milwaukee. He received his M.D. degree from Georgetown University Medical School in 1909 and shortly thereafter joined the U.S. Public Health Service on assignment to St. Elizabeths Hospital in Washington, D.C. In 1913 he was assigned to be a psychiatrist for the Port of New York. In order to help screen the incoming immigrants who spoke a variety of languages, he devised the Glueck Ship Test, a simple test not dependent on language skills. He returned to St. Elizabeths Hospital the following year as a psychiatrist on the Howard Hall Service for the Criminally Insane. During this period (1913–1915) he developed many of his ideas about prisons and forensic psychiatry.

In 1915 he organized the first prison psychiatric clinic in the United States in Sing Sing prison at Ossining, N.Y. He left this post to serve as a captain in the Medical Corps of the U.S. Army in 1918. After leaving the Army he was appointed to the staff of the New York School of Social Work, where he organized a department of mental health and did pioneer work in making psychiatry a major field of instruction. From 1918 to 1923 he was director of the New York Bureau of Child Guidance; during this period he set up the "team" approach, which was to exert great influence on child psychiatry in this country.

In 1927 he established Stony Lodge in Ossining, N.Y., one of the first private hospitals for the psychoanalytic treatment of the mentally ill. While director of this pioneering hospital, he never lost sight of developments in other fields of psychiatry. During one of his frequent trips to Europe in the mid-thirties he observed the work of Manfred Sakel on insulin therapy for schizophrenia. He was so impressed that he wrote the first article on the subject to be published in a major journal in this country. At his own expense he arranged for Dr. Sakel to come to New York to demonstrate his new treatment methods.

Dr. Glueck was a member of many medical organizations including the American Medical Association, the American Psychiatric Association, and the American Psychoanalytic Association. He was particularly active in the American Psychopathological Association, serving as its president in 1945; in 1958 the association honored him by giving him the Samuel W. Hamilton Award.

He wrote over 60 papers on various aspects of psychiatry, ranging from prison psychiatry to psychoanalysis, from insulin treatment to problems of childhood. He was the author of a book titled *Studies in Forensic Psychiatry* and was the translator of important books by Adler, Schilder, and Alexander. During the twenties he was much in demand as a psychiatric expert witness and was one of the psychiatrists called to Chicago by Clarence Darrow to testify in the famous Loeb-Leopold trial in 1924.

Dr. Glueck retired from the directorship of Stony Lodge in 1946 and eventually returned to Washington, D.C., where he worked in several of the outpatient clinics of the Veterans Administration. In 1956 he joined the faculty of the University of North Carolina at Chapel Hill, where he served until he was disabled by a stroke in 1964. During this same period he was senior consultant in psychiatry at the John Umstead Hospital at Butner.

He is survived by his wife, Betty J. Glueck, of Butner; a son (also a psychiatrist), Dr. Bernard Glueck, Jr., of West Hartford, Conn.; a daughter, Dr. Ruth Addison, of Elizabethtown, N.Y.; a brother, Professor Sheldon Glueck of Cambridge, Mass.; two sisters, Mrs. Robert Phillipson and Mrs. Nathan Golden of Washington, D.C.; and five grandchildren.

An imposing figure of a man with his huge frame and massive shock of white hair, he was a familiar sight at psychiatric meetings and made an unforgettable impression whenever he appeared. Invariably kind and patient, he gave younger men freely of his time and shared with them his rich clinical experiences. One of these experiences, which he shared with me, is so characteristic of Dr. Glueck that it bears retelling. During his years of active psychoanalytic practice he once received as a gift a copy of a popular book on law written by one of his analysands who was a famous jurist. The analysis had been eminently successful and on the flyleaf of the book the grateful patient had written the following perceptive inscription: "To Dr. Bernard Glueck—who taught me so many things I already knew." Stories such as this could be repeated by the score and will make Dr. Glueck unforgettable to all who ever knew him.

ZIGMOND M. LEBENSOHN, M.D.

LETTERS TO THE EDITOR

Review Reviewed

SIR: Since the 30-odd books I issued before volume 10 of *Current Psychiatric Therapies* received quite favorable notices both as to content and organization, it would seem picayune to cavil at Dr. David Swenson's recent critique of my editing of that opus (Book Reviews, April 1972 issue). Nevertheless, permit me to quote a few whimsical samples from his review.

"The major categories are inconsistent from volume to volume." True, and so it shall be, since the *Current Psychiatric Therapies* series is intended to reflect varying clinical interests from year to year.

"Although alcoholism is of major importance, there are many other serious addictive and dependency states involving the use of opiates, barbiturates, amphetamines, and many other drugs." True again, but all of them had been treated in special chapters in preceding editions and in two later editions.

"The index of names and the index of subjects are omitted from the table of contents." True once more, on the reasonable supposition that readers other than Dr. Swenson would know that they appear at the end of every book.

"Names and terms in the index are incorrectly referenced." Indices are prepared by a clerk, not the editor, and a representative check revealed only about 22 errors among more than 2,000 entries.

And most amusing: "The content of the articles . . . are generally very good." Yet later: "One also cannot help but wonder about the other aspects of editing, such as selecting and editing the manuscripts and dealing with the authors. . . ." As I explained in the preface, these "aspects," including requesting manuscripts, editing them, and doing considerable rewriting when necessary are indeed the editor's principal responsibility, and I appreciate Dr. Swenson's paradoxical but implicit commendation in this regard.

Should not book reviews also occasionally be edited?

JULES H. MASSERMAN, M.D.
Chicago, Ill.

Editor's Note: Yep, they are edited—but not censored.

Dr. Swenson Replies

SIR: In response to Dr. Masserman I am sorry that he appears to take offense at my review; however, the fact remains —the book was poorly edited.

I will answer his objections in the order of their appearance in his letter.

If one carries a theme designated as a major category from year to year in a series, the theme should be consistent. If changes or modifications are made, they should be well thought out and intentional. The themes should flow smoothly through the series, and if they change too much or too frequently, either poor titles for the major categories were chosen or the titles were whimsically chosen. If the categories change capriciously from volume to volume, how well organized are the topics in the editor's mind? Does he really look at the previous volumes in considering topics for future volumes? If there is no continuity in the series, why is it a series?

A few examples of these inconsistencies follow: "Adult Techniques" in volume 10 was "The Adult" in volume 9; "Individual Therapies" in volume 8, "Individual Psychotherapy" in volume 7; "Adult Psychotherapy" in volume 6, "Individual Psychotherapy" in volume 5 and "Special Techniques with Adults" in volume 4. From the major category titles and the articles listed under them the subjects appear to be very similar, if not identical, and yet the title of the major category changes from volume to volume as if each book was autonomous and not a part of a series.

Another example is "The Child" in volumes 9 and 10, which appeared as "Child and Adolescent" in volume 8, "Child and Adolescent Therapy" in volume 7, "Childhood and Adolescence" in volumes 5, 4, 3, and 2, and "Child and Adolescent" in volume 1.

As for Dr. Masserman's second objection to my review, I still hold that alcoholism is covered more extensively than other addictive and dependency states; for example, volume 10 had four articles on alcoholism and one article on the treatment of heroin "dependence"; volume 9 had one article on alcoholism and one article on "Non-narcotic Psychoactive Drug Dependence"; volume 8 had a major category and three articles on alcoholism and only one article on "Untoward L.S.D. Reactions"; volume 7 had one article on alcoholism and one article on "Cyclazocine in the Treatment of Narcotic Addiction." As far as two later volumes' correcting the inequities, I cannot say, except that the following volume (11) has no articles on alcoholism or drug addiction. Therefore, from the 1967 through the 1971 volumes there have been nine articles on alcoholism and four articles on all the other drug addictions and dependencies combined. That does not appear to me to accurately reflect the "varying clinical interests from year to year" in alcoholism and drug dependency.

As far as omitting the index of names and index of subjects from the table of contents, if everyone knows where they were, why were they listed in the table of contents of all previous volumes? As an editor, I would suspect the index was inadvertently left off the table of contents since it appeared in some form in all the previous volumes. It also seems that the editor cannot make up his mind whether to use "name index" or "index of names," "subject index" or "index of subjects" from volume to volume and even from tables of contents to the sections in the same books. Again, this is a sign of poor editing.

Paying attention to details is an extremely important part of editing. Unfortunately it is not very exciting, but every mistake is multiplied by the number of copies produced and is recorded for all readers to see. If an editor does not want to bother with the monotonous aspects of organizing the publication and editing the manuscripts, galleys, and page proofs, he may also avoid other monotonous aspects of editing, such as making sure he is really reflecting the varying clinical interests from year to year rather than just including in the publication what *he thinks* are the major interests without conscientiously checking them out. Does he take the time and energy to rework a mediocre manuscript on a new or interesting or exciting subject, or does he primarily rely on well-written manuscripts regardless of the topic?

And a good editor should be able to tolerate points of view that differ from his own.

As for errors in the index, the editor, not the clerk, is responsible for what is published; wouldn't it have been better editing to find those 22 errors prior to publication?

Since he should be aware that the book reviews are edited, Dr. Masserman's last question is not clear. Perhaps he means book reviews that are not entirely favorable to him should not be published.

DAVID D. SWENSON, M.D.
Wakefield, Mass.

Journal's Culpa?

SIR: With regard to "The Function of the Dream: A Reappraisal" by Dr. Zvi Giora (March 1972 issue) let me begin by stating that I am disappointed to read an article of such low caliber in the *Journal*.

The author condenses his ideas of the dream theories of Freud, Jung, and Adler into single sentences, none of which is correct due to both inadequacy and inaccuracy. Having set up false targets, he uses the rest of the article to shoot them down. It is revealing that in his list of 24 references, none of the three men he attacks is cited. The fact seems obvious that he is *not* conversant with the works of Freud, Jung, and Adler. His article seems to be a rather dull diatribe that only bears out his "conclusion" that cognition is the "self-same through all levels of existence," presumably referring to rapid eye movement (REM) and non-REM (NREM) sleep, wakefulness, daydreaming, fantasy, fever, skull fracture, etc.

I regret that members of the editorial department allowed this to be published. Presumably their running knowledge of the works of the leaders of psychological dream theory is sufficient to allow them to perceive the trick of substituting a part for the whole.

JULIUS C. TRAVIS
Orinda, Calif.

Dr. Giora Replies

In the only sentence that might be regarded as substantive in his letter, Dr. Travis quotes me as concluding that "cognition is 'the self-same through all levels of existence.' "

The final sentence of my article reads: "The function of cognition will be the self-same throughout all levels of existence . . .," namely, information processing. The précis of the article ends as follows: "Cognition . . . does not change its function through the various states of mind, but its level of organization shifts from state to state."

This is the thesis of my article, and it is stated in it twice. Dr. Travis may judge for himself who is guilty of substituting the part for the whole, thus shooting down false targets.

Putting psychoanalysis in the general frame of information and systems theory, Peterfreund (1) wrote:

> I am taking a unified approach to the phenomena of sleep and waking. In both cases psychological experiences are conceptualized as phenomena which correspond to or parallel the various ever-present information processes in the central nervous system. These experiences include thought, fantasy, and feeling, as well as awareness—the familiar awareness or consciousness of waking, and the awareness or consciousness of sleep, the phenomenon called a dream. Differences in these phenomena are explained in terms of differences in the way information is processed (1, p. 245).

In what follows he explains that during sleep we operate at a lower level of organization, i.e., with diminished inputs and restricted programming: "Although there are fundamental differences in the programming and information inputs during waking and sleep, information processing is continuous."

In the opinion of West (2) dreaming is an experience that occurs when there is a condition of inhibited information input accompanied by cortical arousal. This explains the quality of that information. This change of qualities notwithstanding, "information . . . is continually . . . processed by the living human brain."

This view is substantiated by the well-known fact that mental contents are produced both during REM and NREM periods. The living brain, indeed, never ceases to process information. Therefore we need not speculate about why we dream. Dreaming is one of the phenomena of cognition and has the same function as the other related phenomena. Consequently, in an attempt to understand dreams one has to change his focus and concentrate on the special conditions responsible for dreaming.

Second, the characteristics of dreamy mentation are not contingent upon sleep. Fiss and associates (3) found that subjects who were awakened from REM sleep made up TAT stories that were longer and more complex, visual, bizarre, emotional, and vivid than stories produced after interrupted NREM sleep. That is to say, the distinguishing properties of a sleep stage are not "switched off" following awakening but may continue into the waking state. That dreamy mentation occurs while one is awake will certainly not support theories that rely on an exclusive connection between sleep and dreams.

Such a theory is Freud's dictum that "the normal role" (4) of the dream is to function as a guardian of sleep. What might the dreamy mentation guard while one is awake?

Finally, I would like to note that, as is rather well known, some opponents of Freud preferred to attack him personally rather than to debate his views. To use the same "weapon" against the opponents of Freud would, indeed, be a most ironic way of defending psychoanalysis.

Psyching Out Psi

SIR: Dr. Stanley R. Dean's Letter to the Editor about "Metapsychiatry and the Ultraconscious" (November 1971 issue) came at a propitious time, followed as it was by the Symposium on "Science and Psi: Transcultural Trends," at the 1972 APA

annual meeting in Dallas, Tex., in which Dr. Dean served as coordinator and Dr. Howard Rome as moderator. The study of psychical or psi phenomena has recently won the nod of the American Association for the Advancement of Science. The Parapsychological Association has been admitted to membership, and psychic research is thus well on its way toward integration with other behavioral sciences.

A number of university centers in this country and abroad are engaged in methodical investigations of telepathy, clairvoyance, precognition, psychokinesis, and attempts at unorthodox healing. The general public, broad segments of inquiring youth, and many of our patients are concerned with psi phenomena but grope in the dark or turn for guidance to charlatans and amateur investigators. Some of the research done by experimental parapsychologists is extremely relevant to clinical psychiatry, but most psychiatrists are unfamiliar with it. Or else genuine psi phenomena that may be encountered in psychiatric practice are summarily dismissed as delusion, fraud, or self-deception. Significant contributions made by well-versed psychiatrists are only perfunctorily reviewed in the literature.

Dr. Dean's suggestion to establish an American Metapsychiatric Association and an APA Task Force on Psychic Research or Parapsychology should be hailed by our profession. There can be no doubt that current research warrants a new, open-minded approach to the matter. Whether or not we are dealing here with a new aspect of the unconscious or with altered states of consciousness *and* intentionality deserves serious professional attention and evaluation, as does the relationship of these phenomena to ecstasy, mystical experiences, hypnosis, faith healing, and the like. In particular, attention should be focused on the possibility of psi phenomena in dreams, psychotic reactions, paranoid delusions, alleged reincarnation, and out-of-the-body experiences, as well as in psychotherapy and in primitive healing in various cultures, including our own.

I think, however, that Dr. Dean should clarify his reasons for the need of yet another organization such as the proposed American Metapsychiatric Association (AMPA), and he should make it clear if AMPA would function independently or in liaison with existing organizations.

The important point is to clear the deck for an informed interdisciplinary discussion of the problems; APA should be an active participant in this discussion.

Self-Enucleation: Further Views

SIR: The following account concerns a consultation made in December 1971. I made independent observations that were parallel to and tend to support the speculations of Drs. Rosen and Hoffman in their interesting article "Focal Suicide: Self-Enucleation by Two Young Psychotic Individuals" (February 1972 issue).

The patient was a 22-year-old single male convict who had persistently expressed a desire to have his eyes surgically removed. He had put lighter fluid in his eyes and had been observed poking a lighted cigarette at them. He stated that he wanted to be blind in order "not to see the bad things in the world," such as the "many innocent people who are going to die because of their beliefs next year." After having become blind, he planned to go to a mountaintop and "finish dying" there, after which he would go to another "astral plane." He had made one known suicide attempt, which had been preceded by having his ear pierced.

The patient was the second oldest of five children. His mother often complained of being cursed with the evil eye, and the family believed in black magic. His father had a criminal record and left the family when the patient was age five.

At age 11, when his mother had a "nervous breakdown," he was placed in a foster home. His foster mother seduced him, and he frequently had intercourse with her for about one year.

After dropping out of high school, he enlisted in the Marines and served in Viet Nam. He was court-martialed for having been AWOL several times. His drug use included marijuana and heroin, and he had had several hundred trips on LSD.

Particularly revealing was a vivid dream he had when he was about age 11. He was watching the Last Supper in a house. The house began to rise, going up to Heaven, and the patient grasped a windowsill so that he would be taken along. As the house rose, a pit of snakes was revealed beneath it. He lost his grip and fell into the pit of snakes. The dream then changed to his being alone in a closet. Someone opened the closet and told him he was dead.

A mental status examination revealed blunted affect with appropriate variations, some paranoid ideation, but no current hallucinatory material. His insight and judgment were impaired, and his intelligence was estimated at low normal.

He was transferred to a prison psychiatric facility, where, after several months of supportive therapy without psychotropic medication, he gave up the desire for self-enucleation.

In my discussion of the case I commented that the patient was "really aiming for self-destruction, not just decrease of one specific sensory input." The dream material seemed to indicate both castration anxiety and a wish for self-obliteration, the latter possibly stemming from the former. As with the patients reported by Drs. Rosen and Hoffman, there was a history of LSD usage, religious mysticism, and apparently severe problems of sexual identity.

It may be that some borderline personalities who have severe problems of self-identity, exacerbated by LSD usage, are predisposed toward focal suicide in which castration anxiety is an important motivating force.

A Myth Unmythed

SIR: Dr. Martin Berezin in his article "Psychodynamic Considerations of Aging and the Aged: An Overview" (June 1972 issue) stated that "Rothschild undid the old myth that held to a quantitative correlation between organic brain disease and its clinical behavioral manifestations."

While there may still be many who agree with Rothschild, experimental work such as that of Corsellis (1) suggests that the old myth is not undone, not old, and not mythical.

Indian Peyotists and Alcohol

SIR: I read the article "Navajo Peyote Use: Its Apparent

Safety" by Dr. Robert Bergman (December 1971 issue) with interest. I agree with his plea that attempts should be made to study how Indians seem to use peyote—"a potentially dangerous drug"—safely.

In 1968 I conducted a comprehensive epidemiological study among a large Indian population of Saskatchewan. We were thoroughly frustrated in our attempts to make some estimates of the number of Indian alcoholics since almost every adult appeared to fall within our operational definition of an alcoholic. We therefore decided to find nondrinkers instead, and we found 20 such adults. "We observed that those adults who were once in the habit of drinking heavily, but subsequently gave it up, belonged to the Peyote Cult" (1).

Later during my association with the Saskatchewan Commission on Alcoholism, further evidence convinced me that there is a strong association between nondrinking Indians and the practice of peyote cult as a part of the Native American Church of North America. The precise nature of this association certainly merits further inquiry.

Hyperkinetic Children and the Staccato Syndrome

SIR: In response to Dr. Ernest McCrank's Letter to the Editor "The Staccato Syndrome: A New Definition" (August 1972 issue) I would like to offer some additional remarks stemming from further clinical experience.

It appears now that the history of young people who fall into the category of the Staccato syndrome reveals that they were hyperkinetic as children. Therefore we are considering a triadic system that helps to identify this syndrome as a separate entity: 1) history of hyperkinesis, 2) onset of puberty, and 3) multiple and heavy drug abuse, especially of psychedelics.

It is important, I believe, for child psychiatrists to realize that hyperkinetic children who do not receive proper treatment might become bitter and disappointed and search for instant relief from drugs during adolescence. Fashionable as it is, drug abuse becomes a ticket to peer group acceptance. This becomes especially important to these young people since in their preadolescent years peer participation was unsuccessful. A distinction has to be made here between use of medication and drug abuse. It is clear by now to all child psychiatrists that giving medication to hyperkinetic children is not conditioning them to be victims of drug abuse. Quite the opposite, it prevents deep disenchantment and therefore protects the child to some extent from falling victim to the drug scene. The identity crisis of adolescence is well known, and quite frequently it would be a mistake to equate it with the Staccato syndrome, which occurs rarely.

In summary one can briefly state that carefully following hyperkinetic children into their adolescence would lead to more frequent diagnosis of the Staccato syndrome.

Corrections

Page 452 of the October 1972 issue of the *Journal* contains a minor error that might lead to misinterpretation of the data in the article "Methadone: Some Aspects of Its Legal and Illegal Use," by Weppner, Stephens, and Conrad. Under the heading "Extent of Methadone Use," the second sentence should read: "Further analysis also showed that 65 persons, or 19 percent, had, at some time, both used methadone illegally and participated in a legitimate methadone maintenance program, although not necessarily simultaneously."

The position of one of the authors of the article "The Psychology of Hallucinogenic Drug Discontinuers" in the December 1972 issue of the *Journal* (page 755) was stated incorrectly. Gerald E. Kochansky, Ph.D., is Associate in Psychiatry (Psychology), Harvard Medical School, rather than Assistant Professor of Psychiatry.

BOOK REVIEWS

The Coming of Age, *by Simone de Beauvoir. New York, G.P. Putnam's Sons, 1972, 585 pp., $10.*

This is not a monumental or definitive or original work, nor is it dedicated first and foremost to the nature and miseries of old age. De Beauvoir's book reflects ideology coupled with her own fear and distaste of aging.

Her effort, which she presents as "exhaustive," is marred by major flaws and numerous inaccuracies. She seems totally unaware of important scientific efforts that have endeavored to distinguish the products of disease from the effects of aging per se. Such studies are crucial to understanding the impact of time and to introducing changes into the lives of the elderly. But she vacillates among notions of age as disease, as a "law of life itself," and as a result of socioeconomic conditions. Although the table of contents suggests a comprehensive view of man as he passes through the course of the life cycle, of the interconnections of biology, personality, culture, and economics, the work reads loosely and the essentials of De Beauvoir's thesis are unclear, with the significant exception that she wants to dramatize the cruelty to which old people are subject.

The sections on historical societies and ethnology are excellent, but those on biology and psychology (and psychiatry) are very poor. De Beauvoir did not know of the studies here in the United States at the National Institutes of Health which showed that disease, not age, causes a decline in brain circulation and nutrition. She seems unaware of the extent to which malnutrition, anemia, and a host of illnesses account for the many mental and physical changes observed in old age. She appears uninformed about the landmark studies of psychological development in middle and later life. She must have worked in Parisian libraries from the armchair. Her main empirical sample must have comprised only herself, Sartre, and a few friends. She made few forays among the elderly.

Among her numerous errors are the following. She thinks that intelligence tests were invented in America. (They were devised by the French psychologists Simon and Binet.) She wrongly associates the great scientist Metchnikoff with America. She writes that Dr. Benjamin Spock was 80 in 1968.

De Beauvoir dismisses the labors of that small group of workers in many nations, the gerontologists, for their "positivistic bias" and their methods—which, unlike hers, are at least apt to be based upon empiric study. She fails to note the possibly conscious decisions of governments against supporting fundamental research in aging for fear of possible socioeconomic consequences—and yet it will be through such work that the vigor and quality of old age will be enhanced and not simply life extended.

Particularly troublesome is the realization that De Beauvoir is "using" old people ideologically:

> It is by concentrating one's efforts upon the fate of the most unfortunate, the worst-used of all, that one can successfully shake a society to its foundations . . . it is the exploitation of the workers, the pulverization of society, and the poverty of a culture confined to the privileged, educated few that leads to this kind of dehumanized old age. And it is this old age that makes it clear that everything has to be reconsidered, recast from the very beginning.

And later she says, "Even more scandalous . . . is the treatment that society inflicts upon the majority of men during their youth and maturity."

She states, correctly and memorably, that old people "are called upon to display serenity; the world asserts that they possess it, and this assertion allows the world to ignore their unhappiness." But, at the same time, she overlooks the growing militancy of old people.

She exaggerates: "The aged do not form a body with any economic strength whatsoever and they have no possible way of enforcing their rights"—this in the face of the unmentioned Townsend pension movement in the United States, the evolution of political organizations for old people, the conduct of major class-action legal cases, and so forth.

De Beauvoir seems especially biased against America, which indeed treats its old disgracefully: Over one-fourth of them are impoverished, about 60 percent ill-housed, and many segregated and ridiculed. She is more sympathetic, for good reason, with Scandinavian countries.

In describing personality characteristics De Beauvoir has not moved beyond Aristotle, the famous "ageist," in attributing avarice to old people. She won't accept Freud's explanation by way of "anal eroticism" although, for no clear reason or data, she believes the questionable Freudian explanation of "castration anxiety" as the cause of man's anxiety about death—surprising indeed for an existentialist.

She sees the memories of the old: "Again and again they turn over a few themes of great emotional value to them [clearly not to her]; and far from growing tired of this perpetual repetition, they return to it with an ever greater pleasure. They escape from the present." Yet studies show that recollection in the old has (might I say?) existential meaning, and so is a resolving factor with respect to one's life and one's death.

De Beauvoir is especially pessimistic about sexuality in old age. Masters and Johnson and others have shown the continuing possibilities of sexual activity into very advanced old age. However, De Beauvoir can't stop remarking upon the "degeneration of the sex glands, which is a consequence of aging," while not observing the success associated with endocrine replacement therapy, prostatic surgery, and so forth. She favors erotic experience, but the author of *The Second Sex* (1) is very negative toward the aging female body. And she says of the old man, "He takes pleasure in erotic literature, licentious works of art, dirty stories, the company of young women and furtive contacts; he indulges in fetishism, sado-masochism, various forms of perversion, and . . . after the age of 80, in voyeurism." She cannot possibly substantiate this hostile generalization from any known studies.

Simone de Beauvoir has lent her enormous reputation to a neglected cause—the shameful treatment of the elderly in much of Western civilization. But the benefit she might have brought by her attention to the tragedy of old age and the prejudices and institutions that sustain it is unfortunately offset by her reinforcement of the multitude of stereotypes about aging and the elderly derived from incomplete—and sometimes defective—scholarship, ideology, elitism, and obvious subjectivity. She literally detests aging and the older person in herself.

She is full of self-pity. There are the usual clichés that she is ostensibly opposing:

"Old people find it very hard to adapt themselves to new situations . . . they resist change."

"For every individual age brings with it a dreaded decline."

"Old age . . . reduces emotion."

De Beauvoir is a product of Western civilization, which aims to control nature. (Science and knowledge are prediction and power.) She stands aside of nature and is anguished by its seeming malevolence. "A Frenchwoman, a writer, a person of 60; this is my situation as I live it," she says unconvincingly. "Old age is something beyond my life, outside it—something of which I cannot have any full inward experience," she states more believably.

"It is old age, rather than death," she says, "that is to be contrasted with life. Old age is life's parody, whereas death transforms life into destiny." This again is literature, perhaps, and her special blend of the personal and the doctrinal.

De Beauvoir is unable to see life as a whole, as a process of nature, with aging beginning at conception and progressing toward death. To her, old age is an insult, extraneous, terrifying, and ugly. It is pardonable to suggest that she wrote about old age out of selfish motivation—to grapple with a subject of anxiety to her—as she tried to deal with her feelings and role as a woman in *The Second Sex* and with the death of her mother in *A Very Easy Death* (2). There is nothing wrong with drawing upon one's own experiences; indeed, the autobiographical approach can be creative. But her purpose here is more an act of espousing political doctrine and of self-centered exorcism, wrapped up in mediocre scholarship.

Should her book become a best seller, I hope that it will be an effective consciousness- and conscience-raising device for the liberation of old people. Some readers may come to see that age, a part of life, need not be the contemporary tragedy that it is.

Die schizophrenen Geistesstörungen, *by Manfred Bleuler. New York, Intercontinental Medical Book Corp. (U.S. distributor), 1972, 666 pp., DM 128.*

The changing concept of Eugen Bleuler's schizophrenia is defined clearly by the author who, together with his staff, has spent 30 years in the study and treatment of schizophrenic patients and their families.

The importance of primary symptoms has been replaced by an increasing emphasis on autism, which has become a central point in psychopathology and treatment. Eugen Bleuler recognized the therapeutic importance of the correction of autistic withdrawal by "early discharge" from the hospital, and he later supported "prolonged sleep treatment" to permit therapeutic contact with negativistic and withdrawn patients. The other fundamental feature—disorganization (splitting) of the personality—is now formulated in a broad sense and closely related to autism.

The study of the course of the illness gave much evidence that the outcome may be recovery or a satisfactory social adjustment. In the chronic state, a relatively small number of patients present a picture of deterioration, and even then they can usually be reached. A large number show a definite improvement and, on the average, a worsening does not occur after five years. The clinical subgroups change frequently during a patient's life and are less significant than has been assumed.

The diagnosis of schizophrenia must be based on definite psychopathology, and the concept of latent schizophrenia is rejected. A study among relatives (*Uchtenhagen*) revealed findings in the Rorschach test suggestive of a schizophrenic illness, but these findings occurred with similar frequency among the relatives of brain-damaged patients. Borderline and psychoneurotic schizophrenia are not acceptable diagnoses if severe affective or thinking disorders cannot be established.

The effect of the patient's psychopathology on the members of his family has been well observed in the continuous follow-up studies of former inpatients. Children who appeared schizoid improved markedly when taken away from the family. It is of interest to note that continuous high amounts of chlorpromazine were not necessary. Good results were obtained by continuous psychotherapeutic contact that included the family.

Space does not permit me to review many additional interesting findings. Manfred Bleuler's concept of schizophrenia is close to that of American teaching. On the other hand, signs of thinking disorder are evaluated more critically by him, and diagnosis and treatment are guided by changing psychopathological findings and dynamic factors. Manfred Bleuler's growth was influenced by his own experience and his close contact with other countries, including the United States and France. His book should find an important place in psychiatric libraries.

OSKAR DIETHELM, M.D.
Bronxville, N.Y.

The Making of a Psychiatrist, *by David S. Viscott, M.D. New York, Arbor House, 1972, 410 pp., $8.95.*

This is at least the second of the "making" books about medical specialty training. (There may be more.) Like its predecessor, *The Making of a Surgeon* (1), it is an autobiographical account of residency training—this time, in psychiatry. Incidentally, it is one of the few Book-of-the-Month Club selections to qualify for review in these august pages.

Professionals in the field approach offerings of this kind with a justifiably high index of suspicion because they are often oversimplified, overglamorized, and highly critical. The author obviously anticipates a mixed reception from his colleagues when he predicts in the introduction that "there will be people who think I am a discredit to the profession and fellow psychiatrists who will race to throw the first stone."

A few stones could be thrown, but basically this is a good book. It is entertaining and highly readable, with a cast of characters most of us will readily recognize—the skillful supervisor, the resident in search of Brownie points, the prosperous practitioner worried about his investments, and many others. But the book is more than that; it is also a perceptive, sympathetic attempt to describe some of the training and experience involved in becoming a psychiatrist.

Every resident in psychiatry—and certainly every director of training—will recognize Dr. Viscott's self-portrait instantly, not so much because such residents are common as because they are not easily forgotten. They are often brash, usually impatient, and rarely impressed by standard operating procedures. They keep asking difficult questions, challenging hallowed rituals, and generally making waves. And they nearly always become extraordinarily sensitive psychiatrists.

One of the book's best chapters is titled simply "Techniques." In it, the author talks about therapeutic omnipotence, the therapist's anonymity, and the patient who falls in love with the doctor. ("Unless you're hard up, I mean *really* hard up, you need this like a hole in the head.") Most of his comments are fair and moderate, and all of them are refreshingly free of psychiatric jargon. One possible exception to the "fair and moderate" label may be his highly negative remarks about orthodox psychoanalysis. Some people will agree with him and some will not, but he does perhaps get in a low blow or two.

Obviously Dr. Viscott will not be everybody's model psychiatrist, nor does he aspire to that. Some readers will object to the fact that he takes the whole business too lightly. When asked why he wanted to enter psychiatry, he replied that it seemed "like fun," and for better or worse, that flavor does linger. Not every suicidal patient comes back from a fifth-story ledge (as Dr. Viscott's did) when the therapist tells her it is against the rules to be out there, and not every patient with Hodgkin's disease turns out to be the kind with a good prognosis. In short, the author is much better at depicting the high points of psychiatric experience—the really meaningful insights, the sense of genuine progress—than he is with the frustrations and disappointments and downright agonies that constitute the other side of the coin. He acknowledges this fact obliquely in the introduction when he observes that "I'm not really so much a wise ass as I sometimes seem."

For the psychiatrist, the ultimate test of this kind of book is whether he would hide it from his patients if he could. Most of us, I think, would not. If Dr. Viscott is less solemn than some of us, he is still very serious indeed about the things that matter. He is less hidebound, but he is not kooky. Most of all, he is honest—not omnipotent, not omniscient, capable of error, but warm, empathic, caring, and "in touch with his own humanity."

The last chapter of the book is titled "Postscript: Some Free Advice to Patients in Psychotherapy." The advice is good, and every patient ought to read it. Most psychiatrists had better do the same thing because they are going to hear echoes of it in the office quite soon.

Hartford, Conn.

The Mental Health Service after Unification: Mental Health in a Unified National Health Service—Report of the Tripartite Committee. *London, Journal Department, British Medical Association (distributor), 1972, 95 pp., 50 p (paper).*

While not all of the problems discussed in this British report have been encountered on our shores, others are beginning to plague us. The tripartite committee that wrote this report was composed of members of the Royal College of Psychiatrists, the Society of Medical Officers of Health, and the British Medical Association. Their mission was to consider all aspects of the reorganization of the mental health service in the light of plans to unify the National Health Service as a whole.

The report holds out strongly the necessity for compulsory liaison between the National Health Service and local authorities at all levels. Failure to accomplish this will result in a waste of resources by one of the bodies concerned. The committee also notes that community care has been a popular slogan for the past decade; indeed, the operation of a system of community care is seen by some enthusiasts as almost a panacea, even as a cure for chronic schizophrenia. The committee too strongly supports the concept of community care both for the mentally ill and the mentally subnormal, but as in our own country, it is found to be rudimentary in some districts.

The task of adequately preparing for it will be immense, but only then—if it is successful—will it be prudent to plan for the curtailment or abolition of existing facilities.

Unfortunately, the British authorities have planned as if community care were already "an accepted service of excellence," and thus consider necessary only extremely low rates of beds for the mentally ill (0.5 per 1,000 population). Official policy even now seems to be "running down mental hospitals" and eventually planning to close them altogether. The committee rightly decries this and believes that, with certain exceptions, no plans to close existing mental hospitals should be made until the corresponding community resources are really adequate and efficient. In the meantime, existing hospitals should be sustained in every way.

The committee quotes with approval a statement made by Sir George Godber in his 1968 annual report to the Department of Health and Social Security: "It is important that a patient be treated with one nursing, medical and social work team structure and not be passed from one to the next as a result of some change in his illness or social or legal status." Indeed, this statement might well have served as a text for the committee in all of its deliberations.

This short book is particularly well written and contains more nuggets than can be mentioned here. The report is timely and exceedingly worthwhile. American psychiatrists would do well to read it, for we soon may be faced with comparable problems.

F.J.B.

The Use of Lithium in Psychiatry, *by Barry Maletzky and Paul H. Blachly. Cleveland, Ohio, CRC Press (Chemical Rubber Co.), 1971, 79 pp., $10.50.*

The story of the use of lithium is a fascinating one. Its history, impressive therapeutic results, and increasing contribution to the understanding of the biochemical aspects of recurrent affective disorders combine to make it so. Drs. Maletzky and Blachly take full advantage of the current interest in lithium to give us a monograph that is outstanding in its balance, applicability, and clarity. Many reviews are cluttered and poorly organized, but the most admirable aspect of this one is that it is pared to the informational bone in a most readable way.

The authors review the history of the use of lithium, placing its current application in the perspective of the hypothesized models of, and suggested causative factors involved in, cyclical affective illness. There is a concise summary of the essential findings in over 20 years of studies, including Kline's and Van der Velde's reviews of the world literature. The use of lithium in various clinical conditions is discussed, and its efficacy is compared to that of other treatment modalities. The comments about lithium's prophylactic usefulness are particularly good, as is the comprehensive section on its toxicity.

The authors' outline of the principles of lithium treatment is clear and direct and includes more than operational *guidelines* as they develop the rationale behind their evaluation and treatment outline. The section devoted to lithium's mode of action is characterized by careful attention to a comparison and synthesis of the various hypotheses and study results. The authors

offer interesting and plausible explanations for certain discrepancies reported by different investigators. They explore lithium's effect upon electrolyte balance as well as its relationship to catecholamine metabolism.

In their summary the authors emphasize the demonstrated usefulness of lithium in treating mania, the convincing evidence of its value in the prophylaxis of recurrent affective disorders, and its remarkable safety when administered under controlled conditions. They also suggest additional opportunities for experimental studies. There is an excellent bibliography (355 references), with an addendum of references not included in the main body of the monograph. The authors comment briefly on these 26 additional articles, thereby bringing the literature reviewed up-to-date as of August 1971.

This book is an excellent source for anyone involved in any aspect of lithium usage.

CHARLES W. BOREN, M.D.
Hartford, Conn.

The Therapeutic Community with Chronic Mental Patients, *by Joshua-O. Maller. New York, S. Karger, 1971, 143 pp., $10.55 (paper).*

In *Special Report: Schizophrenia* (1), prepared in 1971 by Loren R. Mosher and David Feinsilver at the National Institute of Mental Health, the following statement appears:

> Unfortunately their introduction [the phenothiazines] seems to have had one not altogether advantageous result. A tendency now exists to rely on drugs to the exclusion of other approaches. Among discharged schizophrenic patients there is a high readmission rate and poor overall community adjustment.

It is to a segment of the patients so neglected that *The Therapeutic Community with Chronic Mental Patients* addresses itself. Joshua-O. Maller, Superintendent of the Pardessia Government Psychiatric Hospital in Israel, describes a program that has been in effect since 1960. He has gradually come to recognize that their hospital is basically a therapeutic community in which many of the principles described by others have been incorporated and adapted to chronic schizophrenic patients. In most cases, their patients have had at least two years of prior psychiatric hospitalization.

Dr. Maller's deeply human approach is apparent. Although I am not familiar with theological existentialism, the philosophical frame of reference in which Dr. Maller describes his community, it is apparent that many of the principles upon which he operates are similar to those I have learned from my own work with chronic schizophrenic patients.

Some of the important principles he discusses include:

1. An active therapeutic approach. He states, "It must not be forgotten that unlike neurotics or psychopaths, in chronics an initial authoritative function must be substituted for the damaged volitional function of the patient."
2. Teaching the entire hospital staff understanding and respect for the chronic mental patient.
3. The creation of an atmosphere of progressive polyvalent communication between patient, staff, family, employer, and other community members.
4. The creation of "the integrated therapeutic community" through establishment of ties to the social community outside. Ideally, the transition from within the hospital to outside it are so gradual and smooth that they are almost imperceptible.
5. A readiness of the institution to readmit former patients and provide assurance of the availability of the hospital's therapeutic community when it is needed.
6. Clear emphasis on the development of a *community* as opposed to a *collective.* To quote Maller:

> Insofar as these meetings respect the integrity and independence of every participant and do not require him to give up certain essentials of existence (freedom, decision-making, self-responsibility) . . . "we" situations are created and the community is formed. Conversely, the collective is based on the principle of collection, of assembling that which is similar and eliminating that which differs.

The statistical tables included show that during the period of February 1, 1960, to December 31, 1966, 457 patients had been admitted to the Pardessia hospital. Of that number, 35 percent had been transferred to locked hospitals and another six percent to custodial hospitals. Only 15 percent had been discharged to their homes. Three percent lived in the hospital but worked outside, and 31 percent were in industrial therapy or occupational therapy within the hospital. Although the treatment seems prolonged and the success rate disappointing, the extremely poor prognosis of the patients treated must be considered.

For me, the extensive theoretical discussion of existential philosophy made difficult reading. Missing were specific examples illustrating the transactions among staff members, patients, and families. Also of value would have been more information regarding the techniques of staff training. I felt, however, that the book had added to the depth of my understanding of the phenomenon with which I had already become familiar in treating chronic schizophrenic patients in a therapeutic community. The reader with no experience in the field might have difficulty grasping the significance of many of the concepts the author elaborates. It is certain, however, that a visit to Pardessia would be enriching.

Washington, D.C.

Homosexuality and Pseudohomosexuality, *by Lionel Ovesey, M.D. New York, Science House, 1969, 157 pp., $8.95.*

This book is a compilation of the author's papers on homosexuality from 1954 through 1963. Of the seven articles, one was co-authored with Willard Gaylin and two with Dr. Gaylin and Herbert Hendin.

The topics covered include Ovesey's view of homosexual conflict: the concept of pseudohomosexual anxiety; the relationship among paranoia, paranoid mechanisms, and pseudohomosexuality; masculine aspirations in women; and the psychotherapy of male homosexuality with comments on prognosis, selection of patients, and therapeutic technique. The last chapter, "Case Studies of Male Homosexuality," describes the treatment of three patients with follow-ups of five or more years. The volume is a significant contribution to our understanding of homosexuality in terms of modern clinical attitudes. Ovesey, among others, has helped to rescue it from the limbo of untreatable conditions (1–3).

Notwithstanding the title, I found that the concept of pseudohomosexuality merits far less emphasis than it has been accorded and constitutes only a minor aspect of Ovesey's work. For example, he states that a heterosexual patient may wish for homosexual gratification but experiences no anticipatory erotic feelings. If such a patient combines this wish and a lack of erotic feelings together with the two nonsexual motivations of dependency and power, he may achieve satisfaction of his dependency and power needs in *fantasy*. This man is said to be suffering from pseudohomosexuality although, at the same time, we are told that he is heterosexual. If he then becomes anxious about this, as revealed in dream material or conscious fantasies, he develops pseudohomosexual anxiety.

Many readers of this volume may easily overlook the fact that Ovesey also includes in this situation a man with the same constellation of factors who then actually engages in homosexual relations to the point of orgasm. Ovesey states that the man had no sexual pleasure prior to the homosexual act, but apparently then does experience sexual pleasure during relations with a same-sex partner. All this he designates as pseudohomosexuality and the anxiety secondary to it as pseudohomosexual anxiety. Evidently he bases his conclusion on the fact that there are no erotic feelings preceding the actual engagement in the homosexual act if, indeed, it does take place, and that the patient is simply using his genitals in the service of other motivations.

It is well known, as Ovesey acknowledges, that homosexual patients, along with their desire for orgastic satisfaction, also seek to gratify their unconscious dependency and power needs when they engage in overt homosexual behavior. That individuals are co-motivated, one motivation rising above the other, and that there is a hierarchical organization of motivations, now one in the ascendancy, now another, was well known to Freud. My own research yielded the finding that the underlying motivation behind *obligatory* homosexuality (i.e., homosexuality arising from inner necessity and a primary feminine identification developed in the preoedipal phase) is ego survival—acquistion of masculinity, albeit temporary, through incorporation of the penis and body of the partner and protection from feelings of weakness and the fear of engulfment at the hands of the mother. Orgastic satisfaction is a concomitant motivation along with gratification of dependency needs and triumphing over the "stronger" male.

Ovesey unfortunately has not taken into account the new research into the classification of homosexuality, which distinguishes between obligatory homosexuality (preoedipal causation) and oedipal homosexuality. The latter form is the manifestation of the negative phase of the oedipal conflict. In these cases the homosexual symptom is ego-alien and therefore there is an absence of conscious erotic excitement. It will usually remain at the level of unconscious thoughts, dreams, and fantasies. Unlike homosexuality derived from the preoedipal phase, it is not a disguised, unconsciously acceptable representation of a deeper conflict (Hanns Sachs's mechanism). When the symptom in a case of oedipal (negative phase) conflict threatens to break into awareness as an erotic feeling, anxiety may develop due to fear of conscience, fear of social censure, and the potential loss of self-esteem. However, under certain conditions, such as defiant rage overriding the restraining mechanism of conscience, periods of intense depression secondary to loss, and the resultant needs for love, admiration, and strength from a person of the same sex, homosexual acts may take place. Such acts, however, do not achieve the magical symbolic restitution as with the preoedipal type, nor is it as inflexible or stereotyped.

Thus Ovesey's pseudohomosexuality is, in my opinion, unconsciously determined *oedipal* homosexuality. This condition, which is often encountered in practice, does not warrant a specialized diagnostic term, thus casting doubt on its correct evaluation as a form of homosexuality.

Apart from these considerations, the author has provided us with a useful publication. Ovesey is to be commended particularly on the manner in which he carefully takes the reader through the difficult periods of therapy: first attempts at heterosexual functioning, the reasons for the interdiction or proscribing of homosexual contacts, dealing with the patient's fear of impotence with women, guilt as resistance, encouragement techniques, and practical advice as to management.

The Physiology of Aggression and Defeat, *edited by Basil E. Eleftheriou and John Paul Scott. New York, Plenum Press, 1971, 305 pp., $13.50.*

This book consists of the proceedings of a special symposium on the Physiology of Aggression and Defeat held at the December 1968 meeting of the Association for the Advancement of Science in Dallas, Tex.

In recent years there has been much emphasis in the psychiatric and other behavioral literature on the social-psychological determinants of aggression and its effects on the "victim," that is, the vanquished or defeated. Some of this literature implies that aggressive behavior with socially important consequences can be adequately understood by taking account only of social, economic, cultural, and other "extraorganismic" variables. Of course, this is not the case. "Intraorganismic" or biological variables are an essential part of the equation and contribute much to the total variance. This book is largely concerned with some of these biological factors, a knowledge of which is essential for understanding aggression as a behavioral phenomenon. This in turn offers the potential for its direction and control in the interest of the commonweal.

The symposium itself contains interesting and valuable contributions, but as a collection the papers do not fit together well. There are some definitional and conceptual problems that require clarification before one can think about so general a term as "aggression." Some clarification is provided in the excellent chapter by K.E. Moyer on physiological models of aggressive behavior, but it alone is not enough. The eight contributions cover an incredibly wide range of topics that bear on the issue of aggression, but in different ways. For example, the impressive research reported by R. Plotnik, D. Mir, and J.M.R. Delgado, in which agonistic behavior was elicited and studied in unrestrained rhesus monkeys by direct electrical stimulation of specific brain sites, is directed at the neurophysiologic *determinants* of behavior. In contrast, the interesting study by P.G. Bourne on altered adrenal function in military combatants in Viet Nam is concerned with adrenocortical steroid *correlates* of aggressiveness.

Other contributions have to do with the effects of sex hormones on the fighting propensities of mice, brain biogenic amine correlates of isolation-induced aggressiveness, and differ-

ential changes in brain macromolecules (e.g., ribonucleic acid) following successful fighting versus defeat. J.P. Scott provides a brief but useful theoretical discussion on the origins and causes of fighting from a genetic, physiologic, and ethologic perspective. This kind of cafeteria sampling does not constitute a well-rounded meal. On the other hand, it should not produce indigestion, since each of the papers is of value in its own right.

It is unfortunate that almost three years elapsed between the symposium and its publication. Some of the research is in rapidly developing areas, and such a delay makes some of the studies a little out-of-date.

In all, this is a useful book by virtue of the caliber of the individual contributions.

JOHN PAUL BRADY, M.D.
Philadelphia, Pa.

Current Psychiatric Therapies, vol. 11, *edited by Jules H. Masserman, M.D. New York, Grune & Stratton, 1971, 213 pp., $14.*

As the editor points out in the preface, this first volume in the second decade of this well-known series sets out to present a wider range of "more comprehensive techniques" in treatment procedures for a series of clinical problems. As might be expected with such an undertaking, the various chapters are not equal in format, style, or even importance, but there are useful hints and suggestions throughout. If there were no other value in the volume than the admonition that the therapist seek therapeutic possibilities outside the standard modalities, it would still be very worthwhile.

The use of computers in the treatment of nonspeaking autistic children, as described by Colby and Smith, is intriguing and may offer some new possibilities in this admittedly discouraging field. Brandes' chapter on the adolescent gets off to a cumbersome start because of the many numerical references (his bibliography is impressive), but he has some practical suggestions, not the least of which is that the therapist must be himself and not try to woo acceptance from his young patients by dressing and talking as they do. Sarrel is equally practical in his management of the difficulties of unwed teen-aged mothers.

In the section on adult techniques, I was a little disappointed that Marcus' chapter on "Gestalt Therapy" and Laqueur's on "Systems Therapy" were not more explicit, for these approaches with a here-and-now flavor seem most appealing for the present-day philosophy. Denmark's brief discussion of the difficulties of psychotherapy with deaf patients deserves careful and thoughtful attention, for there are undoubtedly many similar situations demanding special attention and skills from the therapist.

Huston's chapter on "Treatment of Depressions" covers a great deal of material, but surprisingly does not mention sedatives as preparatory medication for electrotherapy or Indoklon as a possible substitute. Also, lithium carbonate was not suggested as a possible prophylactic medication, although it is certainly true that it is less successful in preventing recurrent depressive episodes than in doing the same for manic recurrences. Shader's chapter on "Drugs and Anxiety" is excellent in its specificity; his error in listing Librium as a meprobamate is obvious. Equally practical are the two following chapters on drugs by Brady and by DiMascio and Shader.

It is worth emphasizing that some symptoms developed by older people may be due to cerebral hypoxia, as suggested by Jacobs and associates. The improvement demonstrated by some of these patients when they are exposed to high concentrations of oxygen should remind us of the possibility that when older persons change living locations from lower to higher altitudes, some difficulties in functioning may occur.

The chapters in the section on marital therapies by Grunebaum and associates, Hollender, and Hansell and associates are all practical guides to choices of therapy for identification of problems and methods of coping with these various difficulties. Hollender's advice that sometimes "no therapy" is the procedure of choice is an often-neglected but very valuable observation.

While mandatory therapy has not often been viewed with enthusiasm, Mathis and Cullens have found it useful in the group treatment of exhibitionists. Seeman advocates a broad application of various treatment modalities—art, music, dance—for his group activities, and these are used in imaginative ways. Grosz reports on the use of ex-patients in the organization called Recovery, Inc.

In the section on community psychiatry, Mike Gorman zeroes in on the delivery of mental health services and in his own inimitable way points out the major distressing defects in health coverage and the absolute necessity of providing some type of national health insurance if we are not to compound the present chaos. His presentation, characteristically, is informed, articulate, and passionate.

A part of this health delivery problem is covered in the section on the various modifications of institutional therapies. Varieties of partial hospitalization are discussed by Feder, Astrachan and colleagues, and Feirstein and associates. Folsom tabulates the importance of staff attitudes in his chapter on "Attitude Therapy in a Hospital Setting."

The volume ends on an international flavor with De Smit's outline description of the crisis center in Amsterdam and with Masserman's outline of the activities of the International Association of Social Psychiatry. In this first issue of the second decade of this series, the new format does provide a good overview of new developments in several interesting and exciting areas, as well as updating some more traditional ones.

C.H. HARDIN BRANCH, M.D.
Santa Barbara, Calif.

Annual Progress in Child Psychiatry and Child Development: 1971, *edited by Stella Chess, M.D., and Alexander Thomas, M.D. New York, Brunner/Mazel, 1971, 607 pp., $15.*

This is the fourth volume in a series that is already having an appreciable impact on the field of clinical and developmental child behavior. Not only is the series establishing itself with busy clinicians as a means of keeping abreast of new advances, but it is also proving itself to be something of a standard setter. Having one's work selected for inclusion amounts to an accolade. Since my work was not included in the year's "outstanding contributions," I can be objective about the book's merits, which are conspicuous.

The book is well edited and attractively printed and in time, along with many others, should make a handsome appearance on the bookshelf. The most striking virtue of the series thus far is the reliability of its appearance each year, which goes to show that, as far as editors are concerned, the best articles are completed articles. The editors are spared all struggles with procrastinators, having only to make their choice and add a few kind words to encourage the reader.

A volume fabricated in this way tends to reflect editorial perspective rather than the current state of the art. If the reader does not see eye to eye with the editor, then the contents, as a

whole, are likely to leave him less than enthralled. The critical factor in general acceptance is whether editors can rise above their own particular frame of reference and search for excellence wherever they can find it. The editors in this case are well known for their "constitutional" approach, so it is not surprising to note that this is fairly well represented in the anthology. One would not, for that matter, expect to find many psychodynamic articles or articles dealing with intrapsychic life, and this is also the case.

Nevertheless, the selection is much wider than in most collections, ranging through cognitive studies, language and learning, social disadvantage and poverty, mental retardation, institutionalization, treatment, and the "now" syndromes of blacks' problems, drugs, and teen-age pregnancy. Selection has also been flexible enough to include the evaluation of psychoanalytic psychotherapy for patients generally excluded from such treatment, indicating that the editors have based their selection, above all, on the evidence of good empirical research. However, even such admirable standards of excellence do not by themselves preclude the admission of contributions that are dull and pedestrian litter in context or presentation, and a certain number of these have crept in (presumably under some disguise), but the good things predominate and compensate for the less rewarding ones.

The ultimate worth of a compendium of this kind can be roughly judged by the memorabilia that can be carried away after a quick reading, and in this respect, this book, like its predecessors, comes out well. We can remember, for example, that institutions need to be evaluated along with their patients, divorce is a family problem, depressed children have depressed mothers, childhood psychosis has a prevalence rate that is one-hundredth that of mental retardation, intelligence is highly sensitive to environment, retarded children may also be deviant, and child neglect is a social as well as an emotional problem. The clinician may know all these things by intuition, but here he has them buttressed with good data.

Where the empirical point of view shows itself most is in the absence of theory, and those interested in contemporary ideas in psychiatry will find themselves relatively disappointed and deprived in this respect. Perhaps theory does not make annual progress!

OFFICIAL ACTIONS

1973 Annual Meeting: Preliminary Program

Following is the preliminary program and other information related to the APA annual meeting, which will be held in Honolulu, Hawaii, May 7–11, 1973. The information here is what was available as of mid-January 1973; it is subject to additions, deletions, and other changes. Included are Registration and Related Information, the Scientific Program, and an Index of Participants. An official booklet containing additional information such as the names of officers of sessions and of discussants, as well as locations, will be distributed in Honolulu at the time of registration.

Registration and Related Information

REGISTRATION

All registration will take place on the mezzanine floor of the Sheraton Waikiki Hotel. The registration desk will be open:

Sunday, May 6—1:00 to 5:00 p.m.

Monday through Thursday, May 7–10—8:00 a.m. to 5:00 p.m.

Friday, May 11—8:00 a.m. to 2:30 p.m.

A registration fee of $10 per day, or $40 for the five days, is required from all nonmembers with the exception of: 1) formally invited participants who are presenting papers or who are session officers, 2) discussants, 3) participants on morning and evening panels, 4) their immediate families, and 5) the immediate families of members of APA. Associate members, members-in-training, and their spouses and immediate families are also exempt from paying registration fees. The fee covers admission to the sessions and includes a badge and a copy of the official program. Badges are required for all sessions (including the opening session) and for the exhibit area. However, a badge does not cover admission to the business session of the Association, which is open only to members.

A $10 registration fee for the five days is required of visitors living outside the United States and Canada and of military personnel on active duty.

A $5 registration fee for the five days is required of the spouses and dependents of all nonmember registrants.

A $5 registration fee for the five days is required of medical students, interns, residents, chaplains, nursing students, students in the mental health professions, and their spouses. Students must present a letter from their school or training facility certifying their status.

The *Scientific Proceedings in Summary Form* for the 1973 annual meeting will be available throughout the week in the registration area at the Sheraton Waikiki Hotel and in the Ballroom Foyer of the Hilton Hawaiian Village.

INFORMATION AND MESSAGE CENTER

The information and message center will be located on the mezzanine floor of the Sheraton Waikiki Hotel and will be manned:

Saturday, May 5—1:00 to 5:00 p.m.

Sunday, May 6—9:00 a.m. to 5:00 p.m.

Monday through Thursday, May 7–10—8:00 a.m. to 5:15 p.m.

Friday, May 11—8:30 a.m. to 2:30 p.m.

Self-service message racks will be available for pickup, deposit, and exchange of messages at all times, even when the message center is closed. Extremely urgent messages will receive the personal attention of APA staff members. All registrants are requested to check the message center periodically.

KEY LOCATIONS

The APA Convention Office will be located in the Ewa Room on the mezzanine floor of the Sheraton Waikiki Hotel. All other APA staff offices will be on the fourth floor of the Sheraton Waikiki.

APA Staff Office	425
Arrangements	428
Information Center	Mezzanine, Sheraton Waikiki
Journal	423
Ladies Hospitality	Niihau Room, mezzanine floor, Sheraton Waikiki
Press Room	426, 427
Program	424

JOURNAL OFFICE

The office of *The American Journal of Psychiatry* will be in

Room 423 (fourth floor) of the Sheraton Waikiki Hotel. The office will be open from 8:00 a.m. to 5:30 p.m., Monday through Thursday, and from 9:00 a.m. to 6:00 p.m. on Friday. Members of the *Journal* staff will be available to discuss any questions that authors who are presenting papers at the meeting may have. They particularly welcome the opportunity to confer with authors about tables and figures to be included in the papers.

It is the policy of the *Journal* to publish only original material that has not been published elsewhere in any form and that is not being considered for publication elsewhere. "Publication" includes recording on videotape or audiotape or appearance in printed form. Specifically with regard to the annual meeting, this policy applies to any material, including new research papers and morning and evening panels, that the authors wish to have considered for publication in the *Journal.*

Authors of numbered papers are reminded that all such papers are the property of the *Journal.* Permission must be secured from the Editor, Francis J. Braceland, M.D., before a paper may be considered for publication elsewhere.

PAPER NUMBERS

Paper numbers are assigned for your convenience in using this preliminary program. These numbers are subject to change. Final numbers will appear in the official APA Program that will be distributed at the annual meeting.

FIRST-AID ROOM

The message and information center of APA will have a list of cooperating physicians. For night emergencies cooperating physicians may be contacted through your hotel switchboard.

MORNING AND EVENING PANELS

Morning panels will be held on Wednesday, May 9, and on Friday, May 11, at 7:00 a.m. Their location will be shown in the official APA Program. Breakfast may be obtained in regular hotel facilities.

Evening panels will be held on Tuesday, May 8, at 7:00 p.m., and on Thursday, May 10, at 5:30 p.m. Their locations will be shown in the official APA Program.

CONTINUING EDUCATION (VIDEOTAPE SPECIAL SESSIONS)

Continuing education sessions are scheduled throughout the week and are presented through the courtesy of Roche Laboratories. All TV sessions will be held in the Dome of the Hilton Hawaiian Village.

FILMS

Films will be shown throughout the week in the Dome of the Hilton Hawaiian Village. A special feature will be shown on Wednesday, May 9, at 2:00 p.m.

EXHIBITS

Technical exhibits will be located on the mezzanine floor of the Sheraton Waikiki Hotel and will be open from Sunday, May 6, at 1:00 p.m., through Thursday, May 10.

Institutional and scientific exhibits will be located in the Tapestry Lounge of the Hilton Hawaiian Village and will be open Monday, May 7, through Thursday, May 10.

ANNUAL BANQUET AND DANCE

The annual banquet and dance will be held on Wednesday, May 9, at 7:30 p.m. in the Coral Ballroom of the Hilton Hawaiian Village. A cocktail party, beginning at 6:30 p.m., will be held in the Roof Garden, which is adjacent to the Coral Ballroom. The cocktail party is included in the price of a banquet ticket.

Tickets may be purchased in advance from Trade Wind Tours, APA Coordinator, P.O. Box 2198, Honolulu, Hawaii 96805, or in the registration area up to 12 noon on Tuesday, May 8.

(A)	Associate	(DM)	Distinguished Member	(I)	Invitee	(M)	Member
(CF)	Corresponding Fellow	(F)	Fellow	(LF)	Life Fellow	(MT)	Member-in-Training
(DF)	Distinguished Fellow	(HF)	Honorary Fellow	(LM)	Life Member		

MONDAY, MAY 7 12:00 P.M.

Session I: Adolescence

2 Psychiatric Hospitalization of Adolescents: A Follow-Up Study
Julian Kivowitz, M.D. (M), Judith Forgotson, M.D. (M), Gerald Goldstein (I), Fred Gottlieb, M.D. (F)

3 The Effect of Childhood Bereavement in Adolescence
Roslyn Seligman, M.D. (F), Goldine Gleser, Ph.D. (I), Joseph Rauh, M.D. (I), Leonard Harris, M.D. (MT)

4 Normal Family Regression at Adolescence
Kent Ravenscroft, Jr., M.D. (M)

5 Prediction of Murder by Adolescents
Derek Miller, M.D. (F), John G. Looney, M.D. (MT)

6 Delinquency and Family Disciplinary Configurations
Melvin Singer, M.D. (M)

Session II: Forensic Psychiatry, Criminal Behavior, and Prisons

7 An Evaluation of Psychotherapy in a Court Clinic
David Lelos, M.A. (I), A. Louis McGarry, M.D. (F), Barbara Popken (I)

8 Psychiatry and the Family Law System
John M. Suarez, M.D. (F), Jan Hunt, J.D. (I)

9 Factors Influencing Criminal Behavior in Newark
Harold S. Feldman, M.D. (M), Robert G. Jarmon (I)

10 Ellsworth House: A Community Alternative to Jail
H. Richard Lamb, M.D. (M)

11 Psychiatric Care in an Overcrowded Prison System
Edward Kaufman, M.D. (M)

12 Jury Selection: Pentagon Papers Trial
Roger L. Gould, M.D. (F), Renee Gould, M.S.C.R.P. (I)

Session III: Peer Evaluation, Certification, and Self-Assessment

13 Evaluation of the Psychiatrist's Performance
Monte J. Meldman, M.D. (F), Rudolf G. Novick, M.D. (LF), Morris B. Squire (I)

14 A One-and-a-Half-Year Experience with Peer Utilization Review
Donald E. Newman, M.D. (F), Herbert S. Goldstein, M.D. (M), Vard Kazanjian, Ph.D. (I)

15 Private Peer Review of Publicly Funded Programs
Allan Levy, M.D. (F)

16 Resident Peer Supervision of Psychotherapy
Daniel K. Winstead, M.D. (MT), Jay S. Bonovitz, M.D. (MT), Melvin S. Gale, M.D. (MT), J. William Evans, M.D. (MT)

17 Board Certification in Psychiatry: New Developments
Stuart M. Finch, M.D. (F), John F. McDermott, Jr., M.D., Christine McGuire, M.A. (I)

18 Results of the 1972 Self-Assessment Program
Hugh T. Carmichael, M.D. (LF), Bryce Templeton, M.D. (M)

Session IV: Psychobiology I

19 An Overview of Immunological Research in Schizophrenia
Joseph H. Autry III, M.D. (MT)

20 CSF Amine Metabolites and Therapies of Depression
Frederick K. Goodwin, M.D. (M), Robert M. Post, M.D. (MT), Dennis L. Murphy, M.D. (M)

21 Thyrotropin-Releasing Hormone in Depression
Arthur J. Prange, Jr., M.D. (F), Ian C. Wilson, M.B. (I), Patricia P. Lara, M.D. (A), Lacoe B. Alltop (I)

22 Effect of Motor Activity on Urinary MHPG in Man
Michael H. Ebert, M.D. (I), Robert M. Post, M.D. (MT), Frederick K. Goodwin, M.D. (M)

23 Muscle Abnormalities in Psychotic Patients
Herbert Y. Meltzer, M.D. (A), Marilyn L. Maas, Ph.D. (I)

Session V: Mental Health and Psychopolitics

24 The Numbers Myth in Community Mental Health
Donald A. Schwartz, M.D. (F), Louise D. Epps, Ph.D. (I)

25 Models in Search of Community Mental Health Programs
Racquel E. Cohen, M.D. (F)

26 Human Resources: A New Direction in Mental Health
Peter G. Bourne, M.D. (M)

27 Great Psychiatric Empires
E. Fuller Torrey, M.D. (M), Robert L. Taylor, M.D. (M)

28 Psychopolitics: Games Politicians Play
Darold A. Treffert, M.D. (F)

29 Emergency Commitment: A Transcultural Study
Michael A. Peszke, M.D. (M), Ronald Wintrob, M.D. (M)

Session VI: Ego Development and Cultural Differences (Joint Panel with the American Psychoanalytic Association)

30 Body, Mind, and Culture Dialectics in Ego Development

Charles A. Pinderhughes, M.D. (M)

31 Socialization, Conservatism, and Personality Development Among Athabaskans
L. Bryce Boyer, M.D. (F), Ruth M. Boyer, Ph.D. (I)

32 Ego Functions and Sociocultural Evolution
Robert A. LeVine, Ph.D. (I)

Session VII: National Commission on Marijuana and Drug Abuse

33 A National Program to Combat Drug Abuse
Dana L. Farnsworth, M.D. (F)

34 Half a Loaf (A Critique of "Marijuana—A Signal of Misunderstanding")
Lester Grinspoon, M.D. (F)

35 Social-Cultural Aspects of Repetitive Drug Use
Louis P. Bozzetti, Jr., M.D. (M)

36 Inside the Commission
Thomas Ungerleider, M.D. (F)

37 The Crusade for Drug Law Reform
Joel Fort, M.D. (I)

Video Session I: Continuing Education (Videotape Special Session)

12:00 Psychodrama Sensitization for Crisis Intervention
Participants: H.L.P. Resnik, M.D. (F), James Enneis (I), Berkley C. Hathorne, Ph.D. (I), Gerald Hecht (I)

1:00 Primary Prevention: Group Meeting with Young Children
Presented by: Sheldon K. Schiff, M.D. (F)

2:15 Multiple Personality: A Reexamination
Participants: Stephen F. Bauer, M.D. (M), Fredric Coplon, M.D. (I), Emanuel Berman, Ph.D. (I), Otto Kernberg, M.D. (F), Merton Gill, M.D. (F), Arnold Ludwig, M.D. (M,

MONDAY, MAY 7 2:00 P.M.

Special Lecture

38 Community Mental Health in Great Britain
Douglas Bennett, M.D., D.P.M. (I), Institute of Psychiatry, The Maudsley Hospital, London, England

MONDAY, MAY 7 8:00 P.M.

Convocation of Eligible Fellows*

Presiding: *Perry C. Talkington, M.D. (LF), President*

Grand Marshalls: *Frances Cottington, M.D. (LF), Richard D. Kepner, M.D. (LF), Thomas W. Sugars, M.D. (LF)*

Music: *The Kamehameha High School Band*

Processional Marches

Invocation: *The Right Reverend Monsignor Charles A. Kekumano, Cathedral of Our Lady of Peace*

Induction of Fellows: *Alfred M. Freedman, M.D. (F), President-Elect*

Presentation of Awards

The William C. Menninger Memorial Convocation Lecture

39 Psychosocial Homeostasis (PSH): Toward a Sociocentric View of Man
Francis L.K. Hsu, Ph.D., Professor of Anthropology, Northwestern University, Evanston, Ill.

* An Eligible Fellow is one who attained such status prior to 1973.

TUESDAY, MAY 8 8:00 A.M.

Session I: Children

40 Are Children Reliable Reporters?
Barbara Herjanic, M.D. (M), Marijan Herjanic, M.D. (F), Freeman Brown (I), Theotis Wheatt (I)

41 Psychiatric Illness in the Pediatric Clinic
Dennis P. Cantwell, M.D. (M)

42 Geographic Mobility and the Military Child
Jon A. Shaw, M.D. (M), Jon Pangman (I)

43 Diagnosis of Mother-Infant Home Behavior
Wells Goodrich, M.D. (F)

44 Attention in Young Children of Psychotic Mothers
Henry Grunebaum, M.D. (F), Justin Weiss, Ph.D. (I), David H. Gallant, Ph.D. (I)

Session II: Studies of Therapeutic Outcome

45 Criteria for Psychotherapeutic Outcome
Peter E. Sifneos, M.D. (F)

46 Individual Versus Group Aftercare Treatment
Marvin I. Herz, M.D. (F), Robert L. Spitzer, M.D. (F), Miriam Gibbon, M.S.W. (I), Kenneth Greenspan, M.D. (M)

47 Blue-Collar Workers in Psychoanalytic Treatment
Nettie Terestman, D.S.W. (I), John J. Weber, M.D. (F), J. David Miller, M.D. (M)

48 CAPS: An Automated Evaluation System
Richard C. Evenson, Ph.D. (I), Ivan W. Sletten, M.D. (F), James L. Hedlund, Ph.D. (I), David M. Faintich (I)

49 The Psychiatric Patient at Work
David B. Robbins, M.D. (M), Arnold J. Kaminer, M.D. (I), Theodore Schussler, J.D. (I), Bernadette M. Teahan, R.N. (I), Isidor H. Pomper, M.S. (I)

Session III: Treatment of Affective Disorders

50 Lithium Prophylaxis in Affective Disorders
Robert J. Prien, Ph.D. (I), Eugene M. Caffey, M.D. (F), C. James Klett, Ph.D. (I)

51 A Guide for Drug Use in Depressive Disorders
Allen Raskin, Ph.D. (I)

52 Drugs and Group Therapy in Neurotic Depression
Lino Covi, M.D. (M), Ronald Lipman, Ph.D. (I), Leonard R. Derogatis, Ph.D. (I)

53 Treatment of Depression by Drugs and Psychotherapy
Gerald L. Klerman, M.D. (F), Alberto DiMascio, Ph.D. (I), Myrna Weissman, M.S.W. (I), Brigitte Prusoff, M.P.H. (I), Eugene S. Paykel, M.D. (M)

Session IV: Studies on Sleep and Dreams

54 Central Pain and Affect: Cortex and Midbrain Sleep
G. LaVonne Brown, M.D. (MT), William P. Wilson, M.D. (F), Blaine S. Nashold, Jr., M.D. (I)

55 Long-Term Drug Effects on Lab Sleep, Home Sleep, Mood
Ernest Hartmann, M.D. (F), James E. Cravens (I)

56 Unpredictable Sleepers: Insomniacs
Robert L. Williams, M.D. (F), Ismet Karacan, M.D. (F)

57 Sleep and Growth Hormone Secretion in Alcoholics
Ekkehard Othmer, M.D. (I), Donald W. Goodwin, M.D. (M), William R. Levine, M.D. (I), William H. Daughaday, M.D. (I)

58 Dreams and Dementia
Milton Kramer, M.D. (F), Thomas Roth, Ph.D. (I), John Trinder, Ph.D. (I)

Session V: Psychiatric Trends and Value Conflicts

59 Psychiatrists Evaluate Treatment: 1961–1972
J. Martin Myers, M.D. (F)

60 Psychiatry's Drift Away from Medicine
Richard A. Schwartz, M.D. (M)

61 Legal and Ethical Aspects of Behavior Control
Seymour L. Halleck, M.D. (F)

62 The Tyranny of Treatment
Jay G. Hirsch, M.D. (F), Gene H. Borowitz, M.D. (F)

63 Community Psychiatry at UCLA: A Decade of Training
Marvin Karno, M.D. (M), John G. Kennedy, Ph.D. (I), Sandra J. Lipschultz (I)

64 Sexual Role Stereotypy: An Issue Within Psychiatry
Leigh M. Roberts, M.D. (F)

Session VI: Transcultural Psychiatry

65 Aggression Among American Indian Tribes
Carl A. Hammerschlag, M.D. (M), Clayton P. Alderfer, Ph.D. (I)

66 Cuna and Otomi Healing Systems: A Comparison
Ricardo Galbis, M.D. (M)

67 The New Soviet Approach to the Unconscious
Nancy Rollins, M.D. (F)

68 Social Psychiatry in Hungary
Gusztav A. Batizy, M.D. (F)

69 Behind Chinese Acupuncture: Hypnosis?
William S. Kroger, M.D. (A)

70 Culture-Bound Neurosis in Japan
Masafumi Nakakuki, M.D. (A)

Session VII: Integrating Psychodynamics and Behavior Therapy (Joint Panel with the American Academy of Psychoanalysis)

71 Psychotherapy: The Restoration of Morale
Jerome D. Frank, M.D. (F)

72 Application of Psychodynamics to Behavior Therapy
John M. Rhoads, M.D. (F)

73 Intensive Group Therapy: An Effective Behavioral-Psychoanalytic Method
Lee Birk, M.D. (M)

74 Empiricism in Psychotherapy: Specification and Measurement
Robert P. Liberman, M.D. (M)

75 Therapy: Gold or Alloy?
Leon Salzman, M.D. (F)

76 Toward a Comprehensive Psychotherapy
Lewis R. Wolberg, M.D. (LF)

New Research

The sessions on new research are being presented again this year. Additional sessions will be held on Wednesday afternoon and on Thursday morning and afternoon. The papers in these sessions will consist of short presentations of recently collected research data. Since every effort was made to include new and exciting data, the papers were submitted after the deadline for printing this program. Consequently, the authors of these papers are not listed here. Program leaflets containing all of the details of the presentations will be available at the registration desk.

Films I: Gestalt Therapy (A New Series of Demonstration Films)*

F1 Questions as Statements
F2 The Little Things That Count
F3 Stuck in Marriage
F4 Polarities in Marriage
F5 Resentment in Marriage
F6 The Layers of Personality
F7 How We Manipulate Others

* This session continues until 11:00 a.m.

TUESDAY, MAY 8 12:00 P.M.

Adolf Meyer Lecture

77 (Title to be supplied)
Paul T.K. Lin, Ph.D. (I), Director, Center for East Asian Studies, McGill University, Montreal, Que., Canada

TUESDAY, MAY 8 2:30 P.M.

Business Session*

President: *Perry C. Talkington, M.D. (LF)*

TUESDAY, MAY 8 7:00 P.M.

Evening Panels

A Gender Identity Disorders: Upon Reflection
Moderator: Jon D. Meyer, M.D. (M)
Panelists: Robert J. Stoller, M.D. (F), Lawrence E. Newman, M.D. (M), Richard Green, M.D. (F), Norman M. Fisk, M.D. (M), Donald R. Laub, M.D. (I)

B Dialogue on Alcoholism
Moderator: John A. Ewing, M.D. (F)

Panelists: Keith S. Ditman, M.D. (F), Jack H. Mendelson, M.D. (F), Robert A. Moore, M.D. (F), E. Mansell Pattison, M.D. (F)

C Community Psychiatry Training: The Resident's View
Moderator: Edward J. Hornick, M.D. (F)
Panelists: Ronald L. Gatsik, M.D. (I), Peter Kimmel, M.D. (I), Humberto L. Martinez, M.D. (I), William R. McFarlane, Jr., M.D. (I), Manuel Trujillo, M.D. (I)

D The Psychotherapy of the Schizophrenic Patient: 1973
Moderator: Gerald J. Sarwer-Foner, M.D. (F)
Panelists: Clarence G. Schulz, M.D. (I), Jarl K. Dyrud, M.D. (I), P. Giovacchini, M.D. (F), John S. Kafka, M.D. (F)

E To What Avail? U.S. and Canadian Drug Commissions
Moderator: J.R. Unwin, M.D. (F)
Panelists: Daniel X. Freedman, M.D. (F), Seymour L. Halleck, M.D. (F), Lionel P. Solursh, M.D. (I), J. Thomas Ungerleider, M.D. (F)

F Mental Health Training in the 70s
Moderator: James S. Eaton, Jr., M.D. (M)
Panelists: Frederick R. Hine, M.D. (F), Dewitt C. Baldwin, Jr., M.D. (M), James Tenzel, M.D. (M), John Romano, M.D. (LF)

G Psychiatry and Foreign Affairs: The India-Pakistan Conflict
Moderator: Vamik D. Volkan, M.D. (F)
Panelists: Jerome D. Frank, M.D. (F), Rita R. Rogers, M.D. (F), Jajdeesh Teja, M.D. (M), Tajammul Bhatti, M.D. (MT), William D. Davidson, M.D. (F)

H Sex Offenders: Psychiatric and Forensic Research
Moderator: Joseph J. Peters, M.D. (M)
Panelists: Hermann A. Roether, Ph.D. (I), Carol D. Bohmer, LL.M. (I), James M. Pedigo, M.D. (M), Eleanor Ross, Ph.D. (I), Lance S. Wright, M.D. (F)

I Effects on Individual Psychology of Changes in Contemporary Morality
Moderator: John S. Kafka, M.D. (F)
Panelists: John C. Nemiah, M.D. (F), Edward D. Joseph, M.D. (F), Jeanne Spurlock, M.D. (F), Norman E. Zinberg, M.D. (F), Frederic T. Kapp, M.D. (F)

J The Psychology of Chess
Moderator: Stuart R. Schwartz, M.D. (M)
Panelists: Richard D. Chessick, M.D. (F), Norman Reider, M.D. (LF), Reuben Fine, Ph.D. (I), Burt Hockberg (I)

K Treatment Contracts in Transactional Analysis
Moderator: John M. Dusay, M.D. (M)
Panelists: William H. Holloway, M.D. (F), David B. Jarvis, M.D. (M), Roberto Kertesz, M.D. (I), John J. O'Hearne, M.D. (F)

L Demonstration of Encounter Techniques
Moderator: William E. Moore, M.D. (M)
Panelist: Nicholas Fish, M.D. (F)

M The Psychiatric Clerkship in the New Curriculum
Moderator: David W. Preven, M.D. (M)
Panelists: Irwin Feinberg, M.D. (M), Leston Havens, M.D. (F), Bryce Templeton, M.D. (M), Sidney Werkman, M.D. (F)

N The Psychiatrist as Organizational Change Agent
Moderator: Carl A. Hammerschlag, M.D. (M)
Panelists: Boris M. Astrachan, M.D. (M), Garrett O'Connor, M.D. (M)

O The Bremer Case: Interpreting Responsibility
Moderator: Jonas R. Rappeport, M.D. (F)
Panelists: Eloise Agger, A.C.S.W. (I), Robert L. Sadoff, M.D. (F), Eugene C. Stammeyer, Ph.D. (I), Eugene B. Brody, M.D. (F), William L. Putzel, J.D. (I)

P Measuring the Teaching of Introductory Psychiatry
Moderator: Paul Miller, M.D. (F)
Panelists: David Cline, M.D. (M), Duane Hagen, M.D. (M), Russell Monroe, M.D. (F), Joe P. Tupin, M.D. (F)

Q Psychiatry and Religion: Task for the 70s
Moderator: Abraham N. Franzblau, M.D., Ph.D. (F)
Panelists: Angelo D'Agostino, M.D. (F), Emanuel M. Honig, M.D. (F), Merritt H. Egan, M.D. (M), Edgar Draper, M.D. (F)

R Metapsychiatry and the Psychic Mystique
Moderator: Ramon Parres, M.D. (F)
Panelists: Stanley R. Dean, M.D. (F), Aristide H. Esser, M.D. (M), George G. Ritchie, M.D. (M), Russell Noyes, M.D. (F)

S Psychiatric Physician's Associates
Moderator: M.J. Short, M.D. (M)
Panelists: Samuel Herring (I), Adrian B. Boone (I), Lois Pennel, R.N. (I), Hal G. Gillespie, M.D. (M), Elizabeth B. Harkins, M.S.W., A.C.S.W. (I)

T The Executive: Choice, Commitment, and Conflict
Moderator: Barrie S. Greiff, M.D. (M)
Panelists: John MacIver, M.D. (F), Duane Hagen, M.D. (M), Margaret Hennig, Ph.D. (I), Stuart Taylor, Ph.D. (I)

U Community Mental Health Programs for Children
Moderator: Michael E. Fishman, M.D. (F)
Panelists: Arthur Carfagni, M.D. (M), Vernon Kliewer, M.D. (M), Thomas M. Haizlip, M.D. (M), C. Wallace Dalley, M.D. (M), Lawrence S. Rubin, Ph.D. (I)

V Sex Education in Medical Schools
Moderator: David B. Marcotte, M.D. (M)
Panelists: Ira Reiss, Ph.D. (I), Harold I. Lief, M.D. (F), Francis J. Kane, Jr., M.D. (F), Takey Crist, M.D. (I), Jay Mann, Ph.D. (I)

W Schizophrenia as Life-Style
Moderator: Werner M. Mendel, M.D. (F)
Panelists: Arthur Burton, Ph.D. (I), Juan J. Lopez-Ibor, M.D. (DF), Loren R. Mosher, M.D. (M), Jordan M. Scher, M.D. (M)

X Eco-Epidemiology in Prevention of Mental Illness
Moderators: A.D. Schwartz, M.D., M.P.H. (M), Robert C. Marvit, M.D., M.Sc. (M)
Panelists: Fred L. Dunn, M.D., D.T.M. & H. (I), John B. Calhoun, Ph.D. (I), Roderic Gorney, M.D. (F), Ernest M. Gruenberg, M.D., D.P.H. (F)

Y The History of Psychiatry in Residency Training
Moderator: Fred M. Sander, M.D. (M)
Panelists: Leo H. Berman, M.D. (F), Dave Musto, M.D. (M), David Werman, M.D. (M), C. Christian Beels, M.D. (M)

Z1 Crisis in the Care of Chronic Patients
Moderator: Marvin I. Herz, M.D. (F)
Panelists: Robert A. McKinley, M.D. (F), June Christmas, M.D. (F), A. Anthony Arce, M.D. (F), Jack Wilder, M.D. (F)

Z2 Young Psychiatrists at NIMH: Boon or Bust?
Moderator: J. David Miller, M.D. (M)
Panelists: David Berenson, M.D. (I), Frank M. Ochberg, M.D. (M), Alan I. Levenson, M.D. (F)

Z3 Psychiatrists in Conflict
Moderator: Raymond W. Waggoner, M.D. (LF)
Panelists: John Visher, M.D. (F), Harold Visotsky, M.D. (F), Judge David Bazelon (I), Joseph G. Perpich, M.D. (MT), Donald Light (I)

Z4 Transcultural Studies of Schizophrenia
Moderator: Robert Cancro, M.D. (F)
Panelists: John S. Strauss, M.D. (M), Lyman C. Wynne, M.D. (F), E. Fuller Torrey, M.D. (M), Martin M. Katz, Ph.D. (I)

Z5 New Directions in Psychiatric School Consultation
Moderator: Gene H. Borowitz, M.D. (F)
Panelists: Spencer A. Ward, M.D. (M), Frank T. Rafferty, M.D. (F), Beatrice Hamburg, M.D. (I), Jay G. Hirsch, M.D. (F), Gaston E. Blom, M.D. (F)

WEDNESDAY, MAY 9 7:00 A.M.

Morning Panels

W1 New JCAH Standards for Psychiatric Facilities
Moderator: Roy Menninger, M.D. (F)
Panelists: Hayden H. Donahue, M.D. (F), Albert G. Sheff, M.D. (MT), Dean Brooks, M.D. (F), John T. Holbrook, M.D. (A), Robert A. Moore, M.D. (F)

W2 Research Training in Psychiatric Residency: Pro and Con
Moderator: James R. Stabenau, M.D. (F)
Panelists: Robert Cancro, M.D. (F), David Hamburg, M.D. (F), Robert Michels, M.D. (F), Daniel X. Freedman, M.D. (F)

W3 Consultation to Community Agencies
Moderator: Stewart E. Teal, M.D. (M)
Panelists: James Spensley, M.D. (M), M. Nawaz Kaleel, M.D. (M), Gerald Coon, M.D. (M), Margaret Steward, Ph.D. (I), Stephen Silberstein, M.D. (M)

W4 Continuing Education of Clergymen in Mental Health
Moderator: Dana L. Farnsworth, M.D. (F)
Panelists: Richard E. Hicks, M.D. (M), Randall Mason, Ph.D. (I), James J. Gill, M.D. (A), Norman A. Clemens, M.D. (F)

W5 Liaison Psychiatry: A Resident Educative Process?
Moderator: Robert O. Pasnau, M.D. (F)
Panelists: Klaus D. Hoppe, M.D. (F), Richard H. Rahe, M.D. (F), Marvin Karno, M.D. (M), Daniel B. Auerbach, M.D. (MT), Burton Roger, M.D. (MT)

W6 Practical Problems of Methadone Treatment
Moderator: Charles P. O'Brien, M.D., Ph.D. (M)
Panelists: John Renner, M.D. (M), Barry M. Ramer, M.D. (F), Jacob Schut, M.D. (M), William F. Wieland, M.D. (M)

W7 Complications of Psychiatric Hospitalization
Moderator: Louis B. Fierman, M.D. (F)
Panelists: Boris M. Astrachan, M.D. (M), Robert K. Davies, M.D. (I), Mehadin K. Arafeh, M.D. (F), Lane Ameen, M.D. (F)

W8 Incentive Reimbursement for Mental Health Staffs
Moderator: David J. Muller, M.D. (M)
Panelists: Jack F. Wilder, M.D. (F), George M. Burnell, M.D. (F), Dennis F. Rupel, M.D. (M), William H. Goodson, Jr., M.D. (M)

W9 Comprehensive Health Plans Might Omit Psychiatry
Moderator: Robert L. Williams, M.D. (F)
Panelists: David Wade, M.D. (F), James Harris, M.D. (F), Marvin Perkins, M.D. (F), Collin Rorrie, M.D. (I), Edward G. Long, M.D. (F)

W10 Myths and Realities: Training the Paraprofessional
Moderator: Muriel K. Taylor, M.D. (M)
Panelists: Maxine K. Anderson, M.D. (M), Delois Brown, R.N.M.S. (I), Helen Nash, Ph.D. (I), William Womach, M.D. (M)

W11 Turning a State Hospital Inside Out: Part II
Moderator: John A. Talbott, M.D. (F)
Panelists: Robert Reich, M.D. (M), Vera Paster, Ph.D. (I), Marvin Herz, M.D. (F), Winifred Winikus, M.S.W. (I), A. Anthony Arce, M.D. (F)

W12 The POMR and Psychiatric Teams
Moderator: Donald R. Fowler, M.D. (M)
Panelists: Richard Longabaugh, Ed.D. (I), Nicholas Nunez, M.D. (M), Clare P. Sullivan, M.A., R.N. (I), Margaret M. Walker, M.S.S.W. (I)

W13 Heart Attack Psychic Factors from CCU to Recovery
Moderator: Edward L. Chesne, M.D. (I)
Panelists: Thomas P. Hackett, M.D. (F), Wilfred Dorfman, M.D. (F)

W14 Adolescent Impulse Disorders
Moderator: Lewis F. Wesselius, M.D. (F)
Panelists: Richard Marohn, M.D. (M), Robert E. Gould, M.D. (F), Edwin Levy, M.D. (F), Doyle I. Carson, M.D. (F)

W15 Recent Research in Memory: Clinical Implications
Moderator: Richard Stillman, M.D. (M)
Panelists: Donald W. Goodwin, M.D. (M), Jared Tinklenberg, M.D. (M), Dennis L. Murphy, M.D. (M), Herbert Weingartner, Ph.D. (I)

W16 New Advances in Transactional Analysis
Moderator: Robert C. Drye, M.D. (F)
Panelists: John M. Dusay, M.D. (M), Stephen B. Karpman, M.D. (I), Pamela J. Levin, R.N. (I)

W17 Child Advocacy: A Review of Progress
Moderator: Jack C. Westman, M.D. (F)
Panelists: Spencer A. Ward, M.D. (M), Brenda G. McGowan, M.S.W. (I), John F. Leonard, M.D. (F), William M. Bolman, M.D. (M)

W18 Continuing Education: Its Application to Psychiatry
Moderator: Hugh T. Carmichael, M.D. (LF)
Panelists: Bryce Templeton, M.D. (M), Donald H. Naftulin, M.D. (F), S. Mouchly Small, M.D. (LF), Shervert H. Frazier, M.D. (F)

W19 The Female Resident Experience: Problems, Pleasures
Moderator: Elissa P. Benedek, M.D. (F)
Panelists: Gail M. Barton, M.D. (MT), Christine Bieniek, M.D. (I), Anne Seiden, M.D. (A), Carol Wolman, M.D. (MT)

W20 Alienation: Existential and Cultural Aspects
Moderator: Frank A. Johnson, M.D. (F)
Panelists: Jordan M. Scher, M.D. (M), Robert J. Lifton, M.D. (F), Alvin R. Poussaint, M.D. (F), Eugene A. Kaplan, M.D. (F), Donald Oken, M.D. (F)

W21 Mental Health in Spanish-Speaking Communities
Moderator: James N. Sussex, M.D. (F)
Panelists: Pedro Ruiz, M.D. (M), Fernando Milanes, M.D. (M), Ricardo Galbis, M.D. (M), Alberto C. Serrano, M.D. (M), Jose R. Lombillo, M.D. (M)

W22 Psychiatry for OEO and Model Cities Programs
Moderator: Kim A. Keeley, M.D. (M)
Panelists: James A. Alford, M.D. (F), Yvonne Connor (I), Charles Wright (I), Chester Pughsley (I), Mary Green, M.S.W. (I)

W23 "The Village System": Health Care Delivery in South Carolina
Moderator: Raymond Ackerman, M.D. (M)
Panelists: Robert L. Chartier, M. of Arch. (I), George C. Means, Jr., M. of Arch. (I), Linda S. Martin, M.S.W. (I), Lilyan R. Klein, R.N. (I), D. Devon Pollard, M.D. (M)

W24 Training in Community Mental Health
Moderator: Israel Zwerling, M.D. (F)
Panelists: E. Mansell Pattison, M.D. (F), Donald G. Langsley, M.D. (F), Richard T. Rada, M.D. (M), Edward J. Hornick, M.D. (F), Allan Beigel, M.D. (M)

W25 Ethical Issues in Correctional Psychiatry
Moderator: Luke I. Kim, M.D., Ph.D. (A)
Panelists: Paul L. Loeffelholz, M.D. (MT), Harold M. Boslow, M.D. (F), Bernard L. Diamond, M.D. (F), T.L. Clanon, M.D. (F)

W26 The Sexually Active Teen-ager: Psychiatrist's Role
Moderator: John C. Nemiah, M.D. (F)
Panelists: Malkah Notman, M.D. (M), Pamela Lowry (I), Cornelia M. Friedman, M.D. (M), Carol Nadelson, M.D. (M)

W27 Issues in Psychiatric Training
Moderators: William Van Veen, M.D. (M), Daniel Offer, M.D. (F)
Panelists: David E. Raskin, M.D. (M), John Racy, M.D. (M), Theodor Bonstedt, M.D. (F), Paul J. Fink, M.D. (F)

WEDNESDAY, MAY 9 9:00 A.M.

Session I: Pregnancy and Abortion

78 Exnuptial Pregnancy in New Zealand
John S. Werry, M.D. (I), Christine M. Taylor (I), Denis G. Bonham, M.D. (I), Ann S. Pearson, M.A. (I)

79 Motivational Factors in Pregnant Adolescents
Francis J. Kane, Jr., M.D. (F), Charles A. Moan, Ph.D. (I), Barbara Bolling (I)

80 Making Abortion Consultation Therapeutic
Cornelia M. Friedman, M.D. (M)

81 This paper was dropped from the program after it had been numbered and set in type.

82 The "Abortion Pseudopsychosis"
Martin M. Bier, M.D. (MT), Frederick S. Mittleman, M.D. (MT)

Session II: Suicide

83 American Indian Suicide: Fact and Fantasy
James H. Shore, M.D. (M)

84 Prognostic Factors in Attempted Suicide
Ari Kiev, M.D. (F)

85 Psychiatric Staff Suicides: Taboo Subject?
Abba E. Borowich, M.D. (MT), Edward D. Joseph, M.D. (F)

86 Observations on Suicide in Chronic Schizophrenics
Paul E. Yarden, M.D. (M)

87 Suicide in Schizophrenia: A Ten-Year Follow-Up
Brenda D. Gurel, Ph.D. (I), Lee Gurel, Ph.D. (I)

Session III: Drugs in the Treatment of Human Aggression

88 Pharmacologic Treatment of Aggression
Russell R. Monroe, M.D. (F)

89 Lithium and Impulsive-Aggressive Behavior
Michael H. Sheard, M.D. (M)

90 Neuroleptics and Newer Psychotropic Agents: The Major Tranquilizers
Turan M. Itil, M.D. (M)

91 Benzodiazepines and the Minor Tranquilizers
Carlos Azcarate, M.D. (M)

92 Hormones and Antihormone Agents
Dietrich Blumer, M.D. (M), Claude J. Migeom, M.D. (M)

93 Effect of CNS Stimulants (Amphetamines) and Other Experimental Agents (Hallucinogens, Narcotics) on Human Aggression
Leon Wurmser, M.D. (F), Willem G.A. Bosma, M.D. (M)

Session IV: Psychobiology II

94 Corticotropin Release During ECT in Man
John P. Allen, M.D. (I), Rebecca F. McGilvra (I), John W. Kendall, M.D. (I), Duane Denney, M.D. (M)

95 Primate Social Isolation: Psychiatric Implications
William T. McKinney, Jr., M.D. (M)

96 Failure of DMT to Evoke Tolerance in Cats
J. Christian Gillin, M.D. (M), Eleanor Cannon (I), Regis L. Magyar (I)

97 Abnormal EEG and Compulsive Eating Disorders
Richard S. Green, M.D. (F), John J. Rau, Ph.D. (I)

98 Electrosleep Therapy: A Double-Blind Trial
Earl D. Hearst, M.D. (I), C. Robert Cloninger, M.D. (I), Eugene L. Crews, M.D. (I), Remi J. Cadoret, M.D. (M)

Session V: Payment Systems for Mental Health Service and Their Consequences

99 High-Quality Low-Cost Prepaid Psychiatric Service
Werner M. Mendel, M.D. (F), Samuel Rapport, M.D. (A), Jann Glasser, M.S.W. (I)

100 A Paradigm of a Complete Third-Party Payment System
Harvey L. Ruben, M.D. (M)

101 Mental Health Coverage Under National Insurance
Robert L. Taylor, M.D. (M), E. Fuller Torrey, M.D. (M)

102 National Health Insurance and Psychotherapy
William L. Granatir, M.D. (F)

103 Third-Party Payment: Transferential Considerations
Sidney S. Goldensohn, M.D. (M), Esther Haar, M.D. (M)

104 The Case for Psychiatric Hospitalization
Charles J. Rabiner, M.D. (F), Abraham Lurie, Ph.D. (I)

Session VI: Transcultural Aspects of Psychiatric Training and Psychopathology

105 Child Psychiatry for Foreign Pediatric Residents
Elisabeth Lassers, M.D. (A), Robert Nordan, Ph.D. (I), Myrna Quintos, M.D. (I), Silviano Gomez, M.D. (I)

106 Meeting Training Needs of State Hospital Residents
William F. Knoff, M.D. (F), Donald Oken, M.D. (F), James A. Prevost, M.D. (M)

107 American Psychiatry for Export: Special Training
John F. McDermott, Jr., M.D. (F), Thomas W. Maretzki, Ph.D. (I), Danilo E. Ponce, M.D. (M)

108 Toward the Assessment of Ethnic-Related Symptoms
Victor Bernal, M.D. (F)

109 Community Psychiatry in a Foreign Country: Malaysia
J. David Kinzie, M.D. (M), J.I. Teoh, M.B. (I), Eng-Seong Tan, M.D. (I)

110 Psychiatry in Hawaii: A Short History
William J.T. Cody, M.D. (F)

Session VII: Should Homosexuality Be in the APA Nomenclature?

111 Stop It, You're Making Me Sick!
Ronald Gold (I)

112 Homosexuality: An Adaptive Consequence of Disorders in Psychosexual Development
Irving Bieber, M.D. (F)

113 Homosexuality and Cultural Value Systems
Judd Marmor, M.D. (F)

114 Should Heterosexuality Be in the APA Nomenclature?
Richard Green, M.D. (F)

115 Criteria for Psychiatric Diagnoses
Robert J. Stoller, M.D. (F)

Video Session II: Continuing Education (Videotape Special Session)

9:00 Medical Marriages
Participants: Robert E. Taubman, M.D. (M), George Saslow, M.D. (M), Paul H. Blachly, M.D. (M), Daniel H. Labby, M.D. (M), Agnar A. Straumfjord, M.D. (M)

10:30 Save the Spouse: Therapy with Young Couples
Participants: Richard A. Crocco, M.D. (M), Leon Robinson, M.D. (M), Jack O. Bradt, M.D. (M)

WEDNESDAY, MAY 9 10:00 A.M.

Benjamin Rush Lecture

116 (Title and author to be supplied)

WEDNESDAY, MAY 9 2:00 P.M.

Session I: Mental Health of Children

117 Endogenous Depression in Infancy and Childhood

Helen J. Ossofsky, M.D. (A)

118 Open-Ended Brief Group Therapy on a Pediatric Ward
Paul C. Laybourne, Jr., M.D. (F), Suzy Shupe, R.N. (I), S. James Sikkema, S.W.S. (I)

119 The Psychological Effects of Childhood Rape
Joseph J. Peters, M.D. (M)

120 Mental Health Services to a Day Care System
Gordon A. Heath, M.D. (M), Vaughn A. Hardesty, Ph.D. (I)

121 The Model Dorm: Changing Indian Boarding Schools
Robert L. Bergman, M.D. (M), George S. Goldstein, Ph.D. (I)

122 Standard Versus Nonstandard English in Group Testing of Black Children
Robert L. Williams, Ph.D. (I), L. Wendell Rivers, Ph.D. (I)

Session II: Trends in Psychiatric Education

123 A Program of Continuing Education in Psychotherapy
Christopher T. Bever, M.D. (F)

124 Research Education: A Core Part of the Residency
Anne M. Seiden, M.D. (A)

125 Comprehensive Training in Forensic Psychiatry
Robert L. Sadoff, M.D. (F)

126 Adapting Videotape Techniques to Levels of Training
Peter G. Wilson, M.D. (F)

127 Behaviors to Motivate Teachers of Human Behavior
Harvey R. Langee, M.D. (M), Alan Arnson, M.D. (M), Ayres D'Costa, Ph.D. (I), Haikaz Grigorian, M.D. (M), F.P. McKegney, Jr., M.D. (M), Ronald Richards, Ph.D. (I)

128 The Solo Woman in a Professional Peer Group
Carol S. Wolman, M.D. (MT), Harold H. Frank, Ph.D. (I)

Session III: Heroin Addiction

129 The Quality of Treatment for Drug Abuse
Frederick B. Glaser, M.D. (M), Freda Adler, Ph.D. (I), Arthur D. Moffett, M.S.W. (I), John C. Ball, Ph.D. (I)

130 Heroin Addiction: Light at the End of the Tunnel
Robert L. DuPont, M.D. (M), Mark H. Greene, M.D. (I)

131 One-Year Follow-Up of Addicted Viet Nam Veterans
Frank Estrada (I), Alex Richman, M.D. (M), Donald W. Morgan, M.D. (M)

132 Heroin Use: "Contagious Disease" or Social Problem?
Donald W. Morgan, M.D. (M), John F. Greden, M.D. (M), Sinai I. Frenkel, Ph.D. (I)

133 Comparison: Inner-City and Suburban Heroin Users
Kenneth G. Schooff, M.D. (M), Eugene Ebner, Ph.D. (I), David G. Lowy, Ph.D. (I), Ronald Hersch, Ph.D. (I)

134 Starch Craving (Pica) in Pregnant Heroin Addicts
Alex Richman, M.D. (M), Jean Gardner, R.D. (I), George Blinick, M.D. (I)

Session IV: Schizophrenia: Outcome Studies

135 The Validity of Schizo-Affective Schizophrenia
V. B. Tuason, M.D. (M), Earl D. Hearst, M.D. (I)

136 Computer EEG: Predictor of Outcome in Schizophrenia
Turan M. Itil, M.D. (M), Bernd Saletu, M.D. (I), John Marasa, M.S. (I), Anthony Mucciardi, Ph.D. (I)

137 Typologies of Outcome of Schizophrenia
Boris M. Astrachan, M.D. (M), Lee Brauer, M.D. (I), Martin Harrow, Ph.D. (I), Carol C. Schwartz, Ph.D. (I)

138 Catatonic Schizophrenia: Prediction of Outcome from Onset
James R. Morrison, M.D. (M)

139 Schizophrenia: Treatment and Follow-Up Worldwide
Elaine Rogan, Ph.D. (I), Thomas M. Sullivan, M.D. (F), H. Warren Dunham, Ph.D. (I)

Session V: Adaptation to Stress

140 Life Changes, Subjective Stress, and Accidents
Melvin L. Selzer, M.D. (F), Amiram Vinokur, Ph.D. (I)

141 The Mortality and the Morbidity of Widowhood
Paula J. Clayton, M.D. (M)

142 Crisis of Separation and Divorce
Gerald F. Jacobson, M.D. (F)

143 Waiting Wives: Women Under Stress
Douglas R. Bey, M.D. (M), Jean Lange (I)

144 A Hope Scale Applicable to Verbal Samples
Louis A. Gottschalk, M.D. (F)

145 Value Priorities, Leisure, Angst, and Joy
Charles M. Gaitz, M.D. (F), Chad Gordon, Ph.D. (I), Judith Scott, M.A. (I)

Session VI: Psychiatric Cross-Cultural Research in Hawaii

146 Stress in a Hawaiian-American Community
Alan Howard, Ph.D. (I)

147 Perceptual Differences in Nurses' Ratings of Patients
Ken Sanborn, Ph.D. (I)

148 The Absent Father Syndrome
Danilo Ponce, M.D. (I), Vincent Lee, M.S.W. (I)

149 Alcoholic Treatment Center at Hawaii State Hospital
Richard Markoff, M.D. (F), William O'Rourke (I), John F. McDermott, Jr., M.D. (F)

150 Psychiatric Consultation to a Filipino Community
Benjamin Young, M.D. (I)

Session VII: Psychiatry and HMOs: Developments on a New Frontier

The first portion of this session will be based on: 1) a survey by the NIMH Task Force on Health Maintenance Organizations (HMOs) of mental health services in nine prepaid medical groups; 2) a federal survey by the Health Services and Mental Health Administration of mental health benefits in HMO prototypes; and 3) a study of HEW Region IX psychiatric HMO-like organizations to develop government policy, guidelines, or applications. In the second part of the session four psychiatrists will report on their experiences directing mental health efforts in prepaid health plans.

151 Mental Health and HMOs: Perspective and Prospects
Herzl R. Spiro, M.D. (F)

152 Marketing Mental Health Benefits to HMOs
Mildred Arrill, M.A., M.S.W. (I)

153 Free-Standing Private Mental Health Programs: Problems and Potentials
Ellen Canepa, M.D., M.P.H. (I)

154 Models of Mental Health Programs in HMO Prototypes
Harold R. Hunter, Ph.D. (I)

155 Oh Management! Oh Productivity!
Jack R. Brown, M.D. (M)

156 Is There a Doctor in the House?
Daniel Y. Patterson, M.D. (M)

157 Current Mental Health Goals in an HMO Model
Robert L. Harrington, M.D. (I), George M. Burnell, M.D. (F)

New Research

The sessions on new research are being presented again this year. Additional sessions were held on Tuesday morning and will be held on Thursday morning and afternoon. The papers in these sessions will consist of short presentations of recently collected research data. Since every effort was made to include new and exciting data, the papers were submitted after the deadline for printing this program. Consequently, the authors of these papers are not listed here. Program leaflets containing all of the details of the presentations will be available at the registration desk.

Films II: Special Feature*

F8 Wednesday's Child

*This session continues until 5:00 p.m.

WEDNESDAY, MAY 9 7:30 P.M.

Annual Banquet and Dance

Presiding Officer: *Perry C. Talkington, M.D. (LF), President*

Presentation of Awards

THURSDAY, MAY 10 8:00 A.M.

Session I: New Models of Mental Health Counseling

158 Teacher-Counselors as Mental Health Intermediaries
Charles R. Keith, M.D. (F), Lucy T. Davis, Ph.D. (I)

159 Mental Health Education for College Professors
John L. Kuehn, M.D. (M), Susanne M. Jensen, Ph.D. (I), Myron Mohr, Ph.D. (I)

160 Affiliative Therapy for Mentally Disturbed Youth
Alan J. Rosenthal, M.D. (M), Josephine R. Hilgard, M.D. (M), Ursula S. Moore, M.S.W. (I)

161 The Peer Counseling Movement
Gordon D. Jensen, M.D. (F)

162 Joint Sexual Counseling by a Husband/Wife Team
Saul H. Rosenthal, M.D. (M), Chauncey F. Rosenthal, R.N. (I)

Session II: Evaluation and Evaluators: New Trends

163 An Evaluation of Evaluations
S. Mouchly Small, M.D. (LF), Peter F. Regan, M.D. (F)

164 Evaluation of Psychiatric Residency Training
George C. Bolian, M.D. (F), Kwong Y. Lum, M.D. (F)

165 Outcome Studies in Psychiatric Evaluation Research
Carol C. Schwartz, Ph.D. (I), Jerome K. Myers, Ph.D. (I), Boris M. Astrachan, M.D. (M)

166 Can the Computer Assist Clinicians in Diagnosis?
Robert L. Spitzer, M.D. (F), Jean Endicott, Ph.D. (I)

167 Computer Diagnosis in Psychiatry: Bayes Approach
R.M.A. Hirschfeld, M.D. (MT), Robert L. Spitzer, M.D. (M), R.G. Miller, Ph.D. (I)

168 Psychiatrists' Evaluations of 50 Journals
Don A. Rockwell, M.D. (F)

Session III: Marijuana

169 Marijuana: Acute, Chronic, and Therapeutic Effects

Ira M. Frank, M.D. (M), Louise D. Epps, Ph.D. (I), Robert Helper, M.D. (I)

170 Marijuana and Physiological Reactivity to Stress
William H. Rickles, Jr., M.D. (M), Michael J. Cohen, Ph.D. (I), Robert S. Naimark (I)

171 Psychosocial Adaptation of College Marijuana Users
Joel S. Hochman, M.D. (A), Richard L. Christie, M.A. (I), Norman Q. Brill, M.D. (LF)

172 Is Marijuana a Drug? Answers from Addicts
Jacob Schut, M.D. (M), Theodora Wohlmuth (I), Karen File, M.U.A. (I), Barbara Naglin, M.S.W. (I)

173 Combat Zone Adjustment: The Role of Marijuana Use
Steven M. Mirin, M.D. (M), Gerald J. McKenna, M.D. (I)

174 Cannabis Indica in 19th-Century Psychiatry
Eric T. Carlson, M.D. (F)

Session IV: Genetics and the Treatment of Affective Disorders

175 CSF Rubidium Metabolism in Depression
David L. Dunner, M.D. (A), Herbert L. Meltzer, Ph.D. (I), Ronald R. Fieve, M.D. (F)

176 Hazards of Lithium Prophylaxis
Gottfried K. Spring, M.D. (M)

177 Lithium Prophylaxis as Determined by Family Study
Julien Mendlewicz, M.D. (I), Ronald R. Fieve, M.D. (F)

178 Research in Genetics and Psychiatry
James R. Stabenau, M.D. (F)

179 Psychiatry, Cytogenetics, and Genetic Mass Screening
Michael A. Sperber, M.D. (A)

Session V: Reactions and Adaptation to Developmental and Situational Stress

180 Sex and the Senior Citizen
Stanley R. Dean, M.D. (F)

181 A New Dimension of the Youth Culture
Armand M. Nicholi, Jr., M.D. (F)

182 The New Morality on the College Campus
Samuel Janus, Ph.D. (I), Barbara Bess, M.D. (M)

183 Partners in Dying
Harold Levine, M.D. (I), Susan P. Levine, M.D. (M)

184 Four Wars, 53 Life Histories: Therapy Implications
Enrique Araneta, Jr., M.D. (A), Phillip Singer, M.D. (I), Carl R. Vann (I)

Session VI: Japanese Americans: A Fusion of East and West

185 Japanese Enterprise and U.S. Middle-Class Values
Joe Yamamoto, M.D. (F), Mamoru Iga, Ph.D. (I)

186 Comparative Symptom Clusters: Japanese Versus Americans
Thomas W. Maretzki, Ph.D. (I)

187 Observations on Verbal Styles in Japanese-Americans
Anthony Marsella, Ph.D. (I), Frank A. Johnson, M.D. (F)

188 Naikan, Morita, and Western Psychotherapy: A Comparison
Takao Murase, M.A. (I), Frank A. Johnson, M.D. (F)

189 Generations and Ethnicity: The Japanese in Honolulu
Colleen L. Johnson, Ph.D. (I)

Session VII: Caveat Doctor! Organic Ills in Psychiatric Clothing (Sponsored by the APA/American College of Physicians Task Force)

Three medical experts will each discuss organic syndromes arising in their field of expertise that mimic psychogenic disease in their symptomatology. Presentations will be made for 20 minutes each covering the following general areas: Dr.

Heath on neurologic disorders (brain tumor, subdural hematoma, multiple sclerosis, cranial arteritis, etc.); Dr. Moser on medical diseases masquerading as psychic disorders; Dr. Escamilla on endocrine disorders (pituitary, thyroid, parathyroid, and adrenal hyper- and hypofunction). A question and answer period will be arranged to round out the program.

Moderator: Robert Heath, M.D. (F)
Panelists: Robert Heath, M.D. (F), Robert Moser, M.D. (I), Roberto Escamilla, M.D. (I)

New Research

The sessions on new research are being presented again this year. Additional sessions were held on Tuesday morning and Wednesday afternoon and will be held on Thursday afternoon. The papers in these sessions will consist of short presentations of recently collected research data. Since every effort was made to include new and exciting data, the papers were submitted after the deadline for printing this program. Consequently, the authors of these papers are not listed here. Program leaflets containing all of the details of the presentations will be available at the registration desk.

Films III: Women in America*

F9 It Happens to Us

F10 Three Lives

*This session continues until 11:00 a.m.

THURSDAY, MAY 10 12:00 P.M.

Session I: Primary Prevention and Childhood Stress

190 This paper was dropped from the program after it had been numbered and set in type.

191 The Social System and Children's Behavior Problems
Graham A. Rogeness, M.D. (M), Richard A. Bednar (I), Herman Diesenhaus, Ph.D. (I)

192 Preventing the Abuse of Little Children
Richard Galdston, M.D. (M)

193 Preventive Implications of Parent Education
Irving N. Berlin, M.D. (F), Roxie Berlin, Ph.D. (I)

Session II: Current Trends and Issues in the Medical School Setting and Graduate Training

194 The Elimination of the Internship in Psychiatry
Byram T. Karasu, M.D. (M), Stefan P. Stein, M.D. (M), Edward Charles, M.A. (I)

195 Six-Year Specialists: A Progress Report
James A. Rugowski, M.D. (I), John R. Marshall, M.D. (M)

196 Time-Limited Medical Student Sensitivity Groups
Stephen S. Dashef, M.D. (I), William M. Espey, M.D. (I), Jeremy A. Lazarus, M.D. (I)

197 Psychiatry Learning System: A Preliminary Report
Patricia M. Randels, M.D. (M), R. Layton McCurdy, M.D. (F), William S. Powell, M.D. (M)

198 Medical School and the Process of Disillusionment
Arthur H. Schwartz, M.D. (M), Marshall Swartzburg, M.D. (M), Julian L. Lieb, M.B.B. Ch. (I), Andrew E. Slaby, M.D. (I)

199 Through the Viewing Tube: Videocassette Psychiatry
David V. Forrest, M.D. (M), James H. Ryan, M.D. (F), Richard Glavin, M.D. (F), H. Houston Merritt, M.D. (M)

Session III: Alcoholism

200 Alcoholism and Allergy

George A. Ulett, M.D. (F), Ellen Itil (I)

201 Alcoholism Service Planning: The Prevalence Survey
Allan Beigel, M.D. (M), E. James Hunter, M.S. (I), John Tamerin, M.D. (M), Edwin A. Chapin, M.S. (I), Mary J. Lowery, M.A. (I)

202 Alcoholism Community Outreach Service in Oklahoma
William Blyth, M.D. (I)

203 Interactional Behavior in an Alcoholic Community
Steven Wolin, M.D. (M), Peter Steinglass, M.D. (M)

204 Androgens and Aggression in Alcohol Addicts
Nancy K. Mello, Ph.D. (I), Jack H. Mendelson, M.D. (F)

205 Alcohol Sensitivity and Ethnic Background
John A. Ewing, M.D. (F), Beatrice A. Rouse, M.Ed. (I)

Session IV: Schizophrenia

206 On Trends in the Diagnosis of Schizophrenia
Judith B. Kuriansky, Ed.M. (I), W. Edwards Deming, Ph.D. (I), Barry J. Gurland, M.B. (I)

207 Schizophrenia: Major and Minor Criteria
Alvin S. Yusin, M.D. (M), Kazuo Nihira, Ph.D. (I), Clement Mortashed, M.D. (M)

208 Primary Process Thinking and Schizophrenia
Martin Harrow, Ph.D. (I), Donald Quinlan, Ph.D. (I)

209 Pleasure-Deficit in Nonpsychotic Schizophrenics
Lawrence Kayton, M.D. (M), Soon D. Koh, Ph.D. (I)

210 Styles of Stimulus Processing and Schizophrenia
Gordon I. Kuster, M.D. (MT), Martin Harrow, Ph.D. (I), Gary J. Tucker, M.D. (M)

211 Sensorimotor Functions and Cognitive Disturbance
Edward W. Campion (I), Patrick A. Kelleher (I), Peter M. Silberfarb, M.D. (MT), Gary J. Tucker, M.D. (M)

Session V: Hospitalization and Its Alternatives

212 Who Goes to the State Hospital Now?
Donald G. Langsley, M.D. (F), Theodore M. Odland, M.D. (M), James T. Barter, M.D. (M), Douglas Moorehead, M.D. (I)

213 Psychiatric Inpatients: Who, Where, and Future
Lucy D. Ozarin, M.D. (F), Carl A. Taube (I)

214 Involuntary Hospitalization: What For and How Long
James Spensley, M.D. (M), James T. Barter, M.D. (F), Donald G. Langsley, M.D. (F), Paul H. Werme, M.A. (I)

215 Alternatives to Commitment
Richard W. Rewey, M.D. (I), Latressa Sternberg, R.N. (I)

216 The Santa Barbara Project
Robert E. Rabe, M.D. (M)

217 The Effect of a CMHC Upon State Hospital Use
George Dyck, M.D. (M)

Session VI: Looking Ahead: Reciprocal Roles for Asian and North American Educators (Joint Sponsorship by the National Institute of Mental Health and the APA Task Force on Foreign Medical Graduates)

218 A View from Japan
L. Takeo Doi, M.D. (I)

219 A View from Indonesia
Kusamonto Setyonegoro, M.D. (I)

220 A View from the Philippines
Baltazar Reyes, M.D. (CF)

221 A View from Malaysia
Eng-Seong Tan, M.D. (I)

Session VII: Sexual Problems

222 Understanding Women Married to Male Homosexuals
Myra S. Hatterer, M.D. (M)

223 Women Who Marry Men Who Were Formerly Women
Richard Green, M.D. (F)

224 Male Nontranssexuals Seeking Sex Reassignment
Lawrence E. Newman, M.D. (M), Robert J. Stoller, M.D. (F)

225 Outcome Study on 39 Exhibitionists
Joseph Steg, M.D. (M), Joseph J. Peters, M.D. (M)

226 Sex Offenders: Personality Traits and Recidivism
James M. Pedigo, M.D. (M), Joseph J. Peters, M.D. (M), Hermann Roether, Ph.D. (I)

227 Etiologies and Psychodynamics of Male Bisexuality
Lawrence J. Hatterer, M.D. (F)

Video Session III: Continuing Education (Videotape Special Session)

12:00 Videotape Effect on Adolescent Societal Attitudes and Behaviors
Participants: Robert C. Marvit, M.D. (M), Dennis G. McLaughlin, M.A. (I), Judy Lind, M.S.W. (I)

1:15 Dying and Bereavement
We're Not Alone
Presented by: Leon N. Shapiro, M.D. (F)

The Physician in the Management of the Dying Patient
Participants: Arthur B. Schuller, M.D. (I), Harold Levine, M.D. (I)

New Research

The sessions on new research are being presented again this year. Additional sessions were held on Tuesday morning, Wednesday afternoon, and Thursday morning. The papers in these sessions will consist of short presentations of recently collected research data. Since every effort was made to include new and exciting data, the papers were submitted after the deadline for printing this program. Consequently, the authors of these papers are not listed here. Program leaflets containing all of the details of the presentations will be available at the registration desk.

THURSDAY, MAY 10 3:00 P.M.

Special Lecture

228 Psychiatric Care in Africa
Tolani Asuni, M.D., D.P.M. (I), Medical Superintendent, the Aro Hospital, Abeokuta, Nigeria

THURSDAY, MAY 10 5:30 P.M.

Evening Panels

AA Depression: An Emergent Public Health Problem
Moderator: Martin M. Katz, Ph.D. (I)
Panelists: James Maas, M.D. (F), Gerald L. Klerman, M.D. (F), Steven Secunda, M.D. (M), Dean Schuyler, M.D. (M), Raymond Friedman, M.D. (M)

BB Problem-Oriented Record and Psychiatry
Moderator: Ralph S. Ryback, M.D. (M)
Panelists: Richard L. Grant, M.D. (M), Ross Grumet, M.D. (M), W.P. Mazur, M.D. (M), Francis P. Kalibat, M.D. (M)

CC Sociopsychiatric Implications of Population Control
Moderators: Jules H. Masserman, M.D. (LF), John J. Schwab, M.D. (F)
Panelists: Roderic Gorney, M.D. (F), Frederick J. Ziegler, M.D. (F), Stephen Fleck, M.D. (F), H. Curtis Wood, Jr., M.D. (I), Erika Freeman, Ph.D. (I)

DD Military Psychiatry: Fact or Fantasy
Moderators: Harvey L. Ruben, M.D. (M), Norman Tamarkin, M.D. (M)
Panelists: Robert J. Lifton, M.D. (F), Douglas Bey, M.D. (A), Henry Friedman, M.D. (M), Peter G. Bourne, M.D. (M), Lt. Col. Frank W. Zimmerman, USAF, MC (I)

EE An Elective Abroad During Residency: Pros and Cons
Moderator: Dennis P. Cantwell, M.D. (M)
Panelists: Sheldon Bloch, M.D. (MT), David Sheffner, M.D. (MT), Ron Thurston, M.D. (MT), Peter Tanguay, M.D. (M), Robert Feldstein, M.D. (M)

FF Child Abuse: New Findings, New Directions
Moderator: Howard Hansen, M.D. (F)
Panelists: Eli Newberger, M.D. (I), George Starbuck, M.D. (I), Joliy K. (I), James Kent, Ph.D. (I), James Apthorp, M.D. (I)

GG Patients' Rights and the Right to Treatment
Moderator: Robert L. Sadoff, M.D. (F)
Panelists: Ames Robey, M.D. (F), Jonas R. Rappeport, M.D. (F), James Thrasher, M.D. (M), Dennis Koson, M.D. (I), Carol Bohmer, LL.M. (I)

HH Current Developments in Electrosleep Therapy
Moderator: Earl D. Heart, M.D. (I)
Panelists: C. Robert Cloninger, M.D. (I), John P. Feighner, M.D. (M), Saul H. Rosenthal, M.D. (M), Rodrigo A. Munoz, M.D. (M)

II Psychiatry's Lack of Responsibility to Medicine
Moderator: Norman B. Levy, M.D. (M)
Panelists: Thomas P. Hackett, M.D. (F), William F. Kiely, M.D. (M), Chase P. Kimball, M.D. (M), Z.J. Lipowski, M.D. (F), Edward J. Sachar, M.D. (M)

JJ Progress in Transcultural Psychiatry
Moderator: Ramon Parres, M.D. (F)
Panelists: Carol Wolman, M.D. (MT), Stanley R. Dean, M.D. (F), Karl J.F. Gossner, M.D. (F), Keith Yonge, M.D. (F), Joe Yamamoto, M.D. (F)

KK The Individual Versus the Group in Group Therapy
Moderator: Donald A. Shaskan, M.D. (LF)
Panelists: Edward L. Pinney, Jr., M.D. (F), Aaron Stein, M.D. (F), Clifford J. Sager, M.D. (F), Hyman Spotnitz, M.D. (LF)

LL A Report from Four Minority Group Mental Health Conferences
Moderator: K. Patrick Okura (I)
Panelists: James Ralph, M.D. (M), Juan Ramos, M.D. (I), David Reisling (I), Jing Hsu, M.D. (M), Larry Koseki (I), Sritham Thanaphum, M.D. (A)

MM Unified Services: Give a Little, Get a Lot?
Moderator: Alvin M. Mesnikoff, M.D. (F)
Panelists: Richard M. Silberstein, M.D. (F), Richard T. Suchinsky, M.D. (F), Manuel Hermida, M.D. (A), Paul Cooper, M.S.W. (I), Stuart L. Keill, M.D. (F)

NN Ethical Issues in the New Sex Education
Moderator: Charles R. Young, M.D. (M)
Panelists: Seymour L. Halleck, M.D. (F), E. Mansell Pattison, M.D. (F), Herbert C. Modlin, M.D. (F), Earl A. Loomis, Jr., M.D. (F), Truman G. Esau, M.D. (M)

OO Mental Health, Psychiatry, and Systems Theory
Moderator: Claudewell S. Thomas, M.D. (F)
Panelists: Boris M. Astrachan, M.D. (M), S. Feldman, D.P.A. (I), H. Halpert, Ph.D. (I), Herzl R. Spiro, M.D. (F), Robert M. Vidaver, M.D. (M)

PP Pacific Basin Psychiatry
Moderator: Frank M. Ochberg, M.D. (M)
Panelists: Robert C. Marvit, M.D. (M), Jack McCants (I), Satoru Izutsu, Ph.D. (I), E.H. Auerswalk, M.D. (M), Frank Haendel, M.D. (M)

QQ Critique and Evaluation of the Therapeutic Community
Moderator: Leo H. Berman, M.D. (F)
Panelists: Marvin I. Herz, M.D. (F), Alan M. Kraft, M.D. (F), Louis B. Fierman, M.D. (F)

RR Recent Research in Schizophrenia: Special Report 1972
Moderator: Loren R. Mosher, M.D. (M)
Panelists: Irwin Feinberg, M.D. (M), Jack Durell, M.D. (F), Leopold Bellak, M.D. (F), Donald L. Burnham, M.D. (F), David Reiss, M.D. (I)

SS How Should We Teach Community Consultation?
Moderator: Allan Z. Schwartzberg, M.D. (F)
Panelists: Irving Schneider, M.D. (F), Alan N. Arnson, M.D. (M), Louis F. Rittelmeyer, M.D. (F)

TT Computerized Psychiatric Information Systems
Moderator: Donald W. Morgan, M.D. (M)
Panelists: Maj. Gregory C. Meyer, M.S.C. (I), Daniel T. Gianturco, M.D. (F), C. Vance Kauzlarich, M.S.I.E., M.S.P.H. (I), James L. Hedlund, Ph.D. (I), Ivan W. Sletten, M.D. (F)

UU Psychosurgical Techniques
Moderator: Edward G. Colbert, M.D. (A)
Panelists: H. Thomas Ballantine, Jr., M.D.(I), Harry R. Bailey, M.D.(I), Evan Davies, Ph.D.(I), Leopold Hofstatter, M.D.(F), M. Hunter Brown, M.D.(I)

VV APA Task Force on Women: Discussion Session
Moderator: Nancy A. Roeske, M.D. (F)
Panelists: Martha Kirkpatrick, M.D. (F), Mary Ann Bartusis, M.D. (F), Anne M. Seiden, M.D. (A), Carol Nadelson, M.D. (M), Leon Eisenberg, M.D. (F)

WW Goals of Medical Student Psychiatric Education
Moderator: Charles L. Bowden, M.D. (M)
Panelists: Lawrence C. Kolb, M.D. (F), Stephen C. Scheiber, M.D. (M), Johnnie L. Gallemore, Jr., M.D. (M), Dan J. Croy, M.D. (M)

XX Family Therapy: A Context Analysis of Don Jackson At Work
Moderator: Andrew Ferber, M.D. (I)
Panelists: Jane Ferber, M.D. (I), John Schoonbeck, Ph.D. (I), C. Christian Beels, M.D. (M)

YY Peace Corps Psychiatry: A Ten-Year History
Moderator: R. Curtis Bristol, M.D. (M)
Panelists: Sidney Werkman, M.D. (F), Arthur Greditzer, M.D. (M), Benjamin Rubenstein, Ph.D. (I), Gene Gordon, M.D. (F), William J. Novak, M.D. (M)

ZZ1 Psychiatry in Genetics: Interdisciplinary Aspects
Moderator: Michael A. Sperber, M.D. (A)
Panelists: J. Silber (I), Alex Capron, LL.B. (I), Albert Morachevski, Ph.D. (I), Lissy F. Jarvik, M.D., Ph.D. (M), Joshua Lederberg, Ph.D. (I)

ZZ2 The Changing Role of Nursing in Psychiatry
Moderator: Abraham Heller, M.D. (M)
Panelists: Sharon Gedan, M.S., R.N. (I), Madeline Leininger, Ph.D., R.N. (I), Fred Kane, M.D. (M)

ZZ3 Art Therapy
Moderator: Paul J. Fink, M.D. (F)
Panelists: Christine E. Sharps, A.T.R. (I), Otto Billig, M.D. (LF), Milton Berger, M.D. (LF), Lynne F. Berger, A.T.R. (I)

FRIDAY, MAY 11 7:00 A.M.

Morning Panels

F1 Impact of Strong Citizen Input on Psychiatric Care
Moderator: Roger Peele, M.D. (M)
Panelists: William M. Bolman, M.D. (M), Hiawatha Harris, M.D. (F), Noland E. Penn, Ph.D. (I), Vivian Smith, M.S.W. (I), Stanley Anderson (I)

F2 Infant Deprivation or Constructive Legislation
Moderator: Mary Elizabeth Remar (I)
Panelists: Bellenden Hutcheson, M.D. (F), Representative Patsy Mink (I), Sarah Woods (I)

F3 Adolescent Sexuality
Moderator: Robert E. Becker, M.D. (M)
Panelists: Robert Cancro, M.D. (F), Robert Steinberg (I), Robert L. Arnstein, M.D. (F), Lorna J. Sarrel, M.S. (I), Philip M. Sarrel, M.D. (I)

F4 What Role for the Psychiatrists?
Moderator: Alvin M. Mesnikoff, M.D. (F)
Panelists: Jack F. Wilder, M.D. (F), Gabriel Koz, M.D. (M), Yoosuf Haveliwala, M.D. (A), Milton Berger, M.D. (LF)

F5 Psychiatry and Race in the Modern South
Moderator: Kim A. Keeley, M.D. (M)
Panelists: John J. Schwab, M.D. (F), Harold W. Jordan, M.D. (A), DeWitt C. Alfred, Jr., M.D. (M), Robert S. McCully, Ph.D. (I), Quinton C. James, M.D. (M)

F6 Psychobiology of Electroconvulsive Therapy
Moderator: Martin Katz, Ph.D. (I)
Panelists: Ferris Pitts, M.D. (F), James McGaugh, Ph.D. (I), Seymour Kety, M.D. (DF), Max Fink, M.D. (F)

F7 Drug Abuse Programs: The National Training System
Moderator: Raymond R. Knowles, M.D. (F)
Panelists: John R. Moore, M.S.W. (I), Tom Carroll, Ph.D. (I), Richard Phillipson, M.D. (I), Vincent Nowlis, Ph.D. (I), Helen Nowlis, Ph.D. (I)

F8 Identifying the Drunk Driver
Moderator: Richard Rada, M.D. (M)
Panelists: Robert A. Moore, M.D. (F), Melvin L. Selzer, M.D. (F), Samuel B. Guze, M.D. (F)

F9 Higher Unit Dosage of Psychotropic Drugs
Moderator: F.S. Abuzzahab, Sr., M.D., Ph.D. (F)
Panelists: Barrett Scoville (I), John M. Davis, M.D. (M), Maurice R. Nance, M.D. (I)

F10 Psychiatry in Southeast Asia: Changing Concepts
Moderator: Gerald J. McKenna, M.D. (I)
Panelists: Ray Fidaleo, M.D. (M), E. Samuel Rofman, M.D. (M), Jonathan Lee, M.D. (MT), John A. Talbott, M.D. (F), Peter G. Bourne, M.D. (M)

F11 Behavioral Factors in Aviation Safety
Moderator: Daniel A. Grabski, M.D. (F)
Panelists: Nolen L. Armstrong, M.D. (M), George I. LeBaron, Jr., M.D. (F), Richard C. Schaeffer, M.D. (I)

F12 Recovery's Cooperation with Professionals
Moderator: Hanus J. Grosz, M.D. (F)
Panelists: Stanley R. Dean, M.D. (F), Bohdana Salaban, M.D. (F), Herbert L. Rooney, M.S.S.W. (I), Harvey M. Freed, M.D. (M), Earl N. Solon, M.D. (M)

F13 The Ethics and Politics of Psychiatric Technology
Moderator: Peter R. Breggin, M.D. (M)
Panelists: Paul Lowinger, M.D. (F), Jonathan Ecker, M.D. (M)

F14 What Therapies Work with Today's College Students
Moderator: Philippa M. Coughlan, Ph.D. (I)
Panelists: Richard Thurell, M.D. (F), Richard N. Jacks, Ph.D. (I), Ira Rudolph, Ph.D. (I), Jerome A. Winer, M.D. (A), Millard Amdur, M.D. (M)

F15 Community Mental Health Training: Past and Future
Moderator: Farrokh Khajavi, M.D. (M)
Panelists: Jerome Wacks, M.D. (A), Albert Gaw, M.D. (I), Jerome Collins, M.D. (M), Joseph Colligan, M.D. (I)

F16 Psychiatric Services to Ethnic Minority Groups
Moderator: Michael A. Woodbury, M.D. (F)
Panelists: Joseph D. Bloom, M.D. (M), Robert L. Bergman, M.D. (I), S. Eugene Long, M.D. (M), Pedro Ruiz, M.D. (A), William J.T. Cody, M.D. (F)

F17 Jungian Psychology in the 1970s
Moderator: Harry A. Wilmer, M.D. (F)
Panelists: James Hall, M.D. (I), John Perry, M.D. (I), Joseph Wheelwright, M.D. (F)

F18 Assessing Motivation in Medical School Applicants
Moderator: John M. Rhoads, M.D. (F)
Panelists: Suydam Osterhout, M.D. (I), James D. Jones, M.D. (F), Daniel T. Gianturco, M.D. (M), Johnnie L. Gallemore, Jr., M.D. (M)

F19 Suicide and Self-Mutilation in Prison
Moderator: George Bach-y-Rita, M.D. (M)
Panelists: Joel Albert, M.D. (MT), Lino Covi, M.D. (M), Russell R. Monroe, M.D. (F), John R. Lion, M.D. (M)

F20 Transcultural Aspects of the Use and Abuse of Drugs
Moderator: Howard P. Rome, M.D. (F)
Panelists: Jack H. Mendelson, M.D. (F), Reginald Smart, Ph.D. (I), Guido Belsasso, M.D. (M), Jean P. Smith, Ph.S. (I)

F21 Mental Health Coverage Under National Health Insurance
Moderator: Milton Greenblatt, M.D. (F)
Panelists: Warren Williams, M.D. (F), Scott H. Nelson, M.D. (M), Robert L. Taylor, M.D. (M), Robert Gibson, M.D. (F)

F22 Psychiatrist-Wife-Mother: Is Serenity Possible?
Moderator: Maryonda Scher, M.D. (F)
Panelists: Elissa Benedek, M.D. (F), Ardis Candy, M.D. (M), Kira Carey, M.D. (I), Bernice Sachs, M.D. (M), Janet Mules, M.D. (I)

FRIDAY, MAY 11 8:30 A.M.

Films IV: Members' Film Theater*

F11 Control of Hyperkinetic and Violent Behavior in Dogs

F12 Diagnosis of Drug Dependence with Naloxone

F13 The Diagnostic Interview in Child Psychiatry

F14 About Sex

F15 Relax and Enjoy It

F16 The Use of Video Replay in Group Psychotherapy

F17 Geel Foster Family Care: 1470–1970

* This session continues until 12:00 p.m.

FRIDAY, MAY 11 9:00 A.M.

Session I: Studies of Individuals at Risk for Schizophrenia

229 Electrophysiologic Studies of High-Risk Children
Turan M. Itil, M.D. (M)

230 A Risk Vulnerability-Intervention Model in Operation
E. James Anthony, M.D. (F)

231 Families in Which Schizophrenia Occurs
Michael J. Goldstein, Ph.D. (I)

232 Children of Deviants
Dorothy L. Miller, D.S.W. (I)

Session II: Depression

233 Effects of Cocaine in Depressed Patients
Robert M. Post, M.D. (MT), Joel Kotin, M.D. (MT), Frederick K. Goodwin, M.D. (M)

234 Ego-Defense Patterns in Manic-Depressive Illness
Steven L. Ablon, M.D. (M), Gabrielle A. Carlson, M.D. (I), Frederick K. Goodwin, M.D. (M)

235 Psychotic Depression and Hallucinations
J. Richard Ciccone, M.D. (I), John Racy, M.D. (M)

236 Thought Disorder in Depression
Benjamin M. Ianzito, M.D. (MT), Remi J. Cadoret, M.D. (M), Daniel D. Pugh, M.D. (M)

237 Divorce, Bereavement, and Depression
C. William Briscoe, M.D. (MT), James B. Smith, M.D. (I)

Session III: Treatments of Heroin Addiction

238 Methadone Self-Withdrawal

S. Parwatikar, M.D. (A), Raymond R. Knowles, M.D. (F), H. Angle, Ph.D. (I)

239 Psychodynamics in Methadone Maintenance
Leon Wurmser, M.D. (F), Willem G.A. Bosma, M.D. (M)

240 Methadone Maintenance and Crime Reduction in Boston
Vernon D. Patch, M.D. (F), Anthony E. Raynes, M.D. (I), Alan Fisch, M.D. (M)

241 Duration of Action of Levomethadyl
Robert Levine, M.D. (M), Arthur Zaks, M.D. (M), Max Fink, M.D. (F), Alfred M. Freedman, M.D. (F)

242 High-Dose Cyclazocine Therapy of Opiate Dependence
Richard B. Resnick, M.D. (A), Max Fink, M.D. (F), Alfred M. Freedman, M.D. (F)

Session IV: Psychopathology I

243 Hysteria and Parental Psychiatric Illness
C. Robert Cloninger, M.D. (MT), Samuel B. Guze, M.D. (F).

244 Introjective Mechanisms in the Paranoid Process
W.W. Meissner, M.D. (M)

245 The Borderline Syndrome: An Operational Definition
Allan B. Willett, M.D. (MT), Franklin D. Jones, M.D. (M), Donald W. Morgan, M.D. (M), Sinai I. Frenkel, Ph.D. (I)

246 Interpersonal Maneuvers of Manic Patients
M. Khaled El-Yousef, M.D. (M), David S. Janowsky, M.D. (M), John M. Davis, M.D. (M)

247 The Natural History of Female Transsexualism
Ira B. Pauly, M.D. (F)

248 A Study of Male Potency Disorders in India
B.R.S. Nakra, M.D. (I), N.N. Wig, M.D. (I), V.K. Varma, M.B. (CF)

Session V: Therapeutic and Antitherapeutic Milieu

249 Dimensions of the Therapeutic Milieu
Lee Gurel, Ph.D. (I)

250 An Egalitarian Model for Inpatient Management
Mark J. Blotcky, M.D. (MT), Donald N. Offutt, M.D. (M), Robert W. Hagebak, Ph.D. (I), Robert P. Stewart, M.S.S.W. (I)

251 Implications of a Changing Hospital Population
Lewis L. Robbins, M.D. (LF)

252 Termination and Transfer in a Psychiatric Hospital
David A. Berkowitz, M.D. (I)

253 On the Stanton-Schwartz "Syndrome"
Herman C.B. Denber, M.D. (F)

254 Seclusion Room: Its Role in Psychiatric Practice
Robert Plutchik, Ph.D. (I), Byram T. Karasu, M.D. (M), Barbara Siegel (I), Hope R. Conte, M.A. (I)

Session VI: Eskimo Psychiatry

255 Eskimo Perception of Psychopathological Behavior
Hugh M. Sampath, M.D. (M)

256 The Arctic Hysterias and the Calcium Hypothesis
Edward F. Foulks, M.D. (M)

257 Eskimo Suicidal Behavior
Robert F. Kraus, M.D. (M)

258 Augumangia-Ukamiarik: Eskimo Sleep Paralysis
Joseph D. Bloom, M.D. (M), Richard D. Gelardin, M.Ed. (I)

Session VII: Psychiatry of the Future: Training Now?

259 New Directions in Residency Training: A Yale Model

Leonard S. Zegans, M.D. (M), Morton F. Reiser, M.D. (LF)

260 The Developmental-Adaptational Approach to Residency Training
Robert Cancro, M.D. (F), Robert E. Becker, M.D. (M), James Stabenau, M.D. (F)

261 Psychiatric Residency Education in the 60s and 70s
Edgar Draper, M.D. (F)

262 Changes in Medical Education: Implications for Revisions in Residency Training
Carl Eisdorfer, M.D. (M)

FRIDAY, MAY 11 1:00 P.M.

Session I: Stimulants in Hyperkinesis and Schizophrenia

263 Methylphenidate Effects in Learning Disability in Children
Rachel Gittelman-Klein, Ph.D. (I), Donald F. Klein, M.D. (F)

264 Long-Term Side Effects of Stimulants in Children
Daniel J. Safer, M.D. (M), Richard P. Allen, Ph.D. (I)

265 Methylphenidate or Reinforcement?
Irwin S. Jacobs, M.D. (M), Robert E. Anderson, Ed.D. (I)

266 Multimodality Treatment of the Hyperkinetic Child
Anne C. Feighner, M.S.W. (I), John P. Feighner, M.D. (M)

267 Antagonistic Effects of Physostigmine and Methylphenidate
David S. Janowsky, M.D. (M), M. Khaled El-Yousef, M.D. (M), John M. Davis, M.D. (M)

Session II: New Models and Styles in Psychiatric Residency

268 Self-Determination of Psychiatric Residents
Joseph K. Youngerman, M.D. (I), Edward A. Volkman, M.D. (I)

269 Confrontation, Activism, and Residency Change
Stephen B. Levine, M.D. (MT), Eric W. Jensen, M.D. (I), Robert S. Weiss, M.D. (I)

270 A New Model for a Psychiatric Residency
Irene Labourdette, M.D. (I), Lawrence Rockland, M.D. (F)

271 Teaching Community Psychiatry
James E. Sabin, M.D. (M), Steven S. Sharfstein, M.D. (I)

272 Problems of Residents in Community Psychiatry
Paul J. Fink, M.D. (F)

Session III: Drug Use and Abuse

273 Drug Use in Southeast Asia: A Situational Response
Gerald J. McKenna, M.D. (I), Steven M. Mirin, M.D. (MT)

274 The Changing Drug Scene: 1970–1972
John F. Greden, M.D. (M), Donald W. Morgan, M.D. (M), Sinai I. Frenkel, Ph.D. (I)

275 Opium Smoking in Laos: A Survey of 40 Addicts
Joseph Westermeyer, M.D. (M)

276 Student Drug Use: Risk Taking and Alienation
Beatrice A. Rouse, M.Ed. (I), John A. Ewing, M.D. (F)

277 Heroin Use as an Attempt to Cope: Clinical Observations
Edward J. Khantzian, M.D. (M), John E. Mack, M.D. (F), Alan F. Schatzberg, M.D. (I)

278 Alcohol and Drug Abuse: Causes of Sudden Death
Kim A. Keeley, M.D. (M), Peter Kahn (I), Martin H. Keeler, M.D. (F)

Session IV: Psychopathology II

279 National Trends: Changes in Psychiatric Syndromes
Elizabeth Mary Remar (I), Peter B. Hagopian, M.D. (LF)

280 P-B System for Blind Analysis of Manifest Dreams
Albert M. Biele, M.D. (F), Zygmunt A. Piotrowski, Ph.D. (I)

281 Cognitive Response to Erotic and Stressful Films
Mardi J. Horowitz, M.D. (F), Stephanie S. Becker, M.A. (I)

282 Does Psychiatry Have a Common Language?
William D. Weitzel, M.D. (M), Donald W. Morgan, M.D. (M), James A. Robinson (I)

283 Loose Association: Fact or Fantasy?
Andrew Siegel, M.D. (M), Frank E. Reilly, M.D. (I), Martin Harrow, Ph.D. (I), Gary J. Tucker, M.D. (M)

284 The Hysterical Personality in Males
Paul V. Luisada, M.D. (I), Roger Peele, M.D. (M), Elizabeth A. Pittard (I)

Session V: Social Psychiatry and Consultation

285 Tertiary Prevention in a Disabled Population
Stuart L. Keill, M.D. (F), Sylvan S. Furman, M.A. (I)

286 CMHC Accessibility: A Survey of the Rural Poor
Soong H. Lee, M.D. (M), Daniel T. Gianturco, M.D. (M)

287 Preventive Mental Health for a Non-Health Agency
Scott H. Nelson, M.D. (M), Paul Batalden, M.D. (I), David P. Kraft, M.D. (I), Frederick J. Stoddard, M.D. (I)

288 Psychiatric Consultation in Government Agencies
David E. Raskin, M.D. (M)

289 The Uniform Experiment
James H. Tenzel, M.D. (M), Victor Cizanckas (I)

Session VI: Evaluation and Change of Mental Health Services

290 A Systems View
Claudewell S. Thomas, M.D. (F)

291 "Whistle Blowers": Nader's Study and Potential Change
Franklin D. Chu (I)

292 Other Thorns in the Side of Bureaucrats: A Review
Gerald L. Klerman, M.D. (F)

293 Mirror, Mirror on the Wall: NIMH Evaluative Strategy
Harry P. Cain II, Ph.D. (I), William R. Tash, Ph.D. (I)

294 PR Aside: NIMH's Major Findings
Charles Windle, Ph.D. (I), Carl A. Taube (I), Rosalyn D. Bass, M.A. (I)

295 Using Study Results: The Birth of a New Idea
Hans M. Schapire, M.D. (F), Charles Windle, Ph.D. (I)

Session VII: Predictors and Follow-Up in Psychiatric Inpatients

296 Short Versus Long Hospitalization: Preliminary Results of a One-Year Follow-Up
Ira Glick, M.D. (F), William A. Hargreaves, Ph.D. (I), Michael D. Goldfield, M.D. (M)

297 A Ten-Year Follow-Up Study of 55 Adolescents
Elizabeth Herrera, M.S.W. (I), Betty G. Lifson, M.S.W. (I), Ernest Hartmann, M.D. (F), Maida Solomon (I)

298 A Six-Month Follow-Up of Drug-Abusing Psychiatric Inpatients
Donald F. Klein, M.D. (F), Melvin Cohen, Ph.D. (I)

299 Predictors of Outcome in Schizophrenia
John S. Strauss, M.D. (M), William T. Carpenter, M.D. (M)

Listed below are the names of those individuals presenting scientific papers and participating in panel discussions and seminars.

Numbers. Numbers following the names refer to paper numbers rather than to pages.

Morning Panels. Morning panels are designated by the following abbreviations: either the letter "W" (for Wednesday) or "F" (for Friday), followed by the number of the morning panel. Thus the abbreviation "M. Pan. W2" refers to panel number 2 on Wednesday morning.

Evening Panels. Evening panels are designated by the following abbreviations: either a single letter for panels on Tuesday evening or double letters for panels on Thursday evening. Thus the abbreviation "B" refers to a panel on Tuesday evening, and the abbreviation "BB" refers to a panel on Thursday evening. Since there are a greater number of evening panels than there are letters in the alphabet, numbers will follow the designations "Z" and "ZZ" for panels on Tuesday and Thursday evenings, respectively. The abbreviations "Z1" and "ZZ3" (for example) are not to be confused with the abbreviations for morning panels.

Video Sessions. The program contains three video sessions, one each on Monday afternoon, Wednesday morning, and Thursday afternoon. These are designated by the following abbreviations: either the letter "M" (Monday), "W" (Wednesday), or "Th" (Thursday), followed by "A" or "P" (for a.m. or p.m., respectively), followed by the video session number. Thus "M/P/Video I" refers to Video Session I on Monday afternoon.

Unnumbered Talk. The program contains only one regular session that does not have numbered papers. This session is designated by the abbreviation "Th/A/VII," which refers to Session VII on Thursday morning.

Advance Registration

ADVANCE REGISTRATION is again available to all APA members and their spouses free of charge.

STUDENTS AND RESIDENTS in the mental health field and their spouses may register in advance. A registration fee of $5 for each person must accompany the advance registration form. Please have your director sign this application form, certifying your status as a student. Please complete the form below and return it to this office, together with your check, not later than Saturday, March 31, 1973. Submit one form for each member. Request additional copies from the Convention Office of the APA.

ADVANCE REGISTRATION FORM

RETURN IMMEDIATELY TO:

Convention Office
American Psychiatric Association
1700 Eighteenth Street, N.W.
Washington, D.C. 20009

Students/Residents
check here:
☐

NAME _____

ADDRESS _____

CITY _____ STATE _____ ZIP _____

In order to receive your Advance Registration in the mail, this form must be received not later than Saturday, March 31, 1973.

If your spouse wishes to register in advance, please print name as it should appear on badge.

NAME _____

I hereby certify that the above named is a student/resident in my training program.

_____
(signature)

_____
(institution)

Reservations

Make all checks payable to "TCI-APA ANNUAL MEETING ACCOUNT" and send required payments and this form to: APA Coordination Center, 1025 Connecticut Avenue, N.W., Washington, D.C. 20036; telephone (202) 569-9555. This reservation form will not be processed unless advance hotel deposit is attached.

RESERVATIONS FORM

1. MAILING ADDRESS (Immediate family should be included on same form with registrant. Others should submit separate form.)

LAST NAME _____

AFFILIATION _____

STREET ADDRESS _____

CITY, STATE, ZIP CODE _____

SPOUSE'S FIRST NAME (if accompanying) _____

CHILDREN'S NAME(S) AND AGE(S) (if accompanying) _____

Accompanying family members who are not residing in the same household should submit a separate form.

2. HONOLULU HOTEL ACCOMMODATIONS (Waikiki Beach Area). An advance deposit of $50 per room is required. Failure to indicate three choices of hotel may delay confirmation. If accommodations are not available at any of the hotels selected, the Coordination Center will make your reservation at another suitable hotel.

A. My first three choices of hotel are:

(Please check rate category for each hotel choice.)

	Standard	Medium	Superior	Deluxe
1. _____	☐	☐	☐	☐
2. _____	☐	☐	☐	☐
3. _____	☐	☐	☐	☐

B. Confirm for my arrival on _____ (date) and departure on _____ (date).

C. Please reserve ☐ single ☐ twin ☐ triple (roll-away bed) room(s).
(Indicate number in box if more than one room.)

D. Please reserve ☐ parlor and 1 bedroom. ☐ parlor and 2 bedrooms.

[1]Indicates that suites are available. Rates for parlor and one bedroom suites range from $40–110. Rates for parlor and two bedroom suites range from $55–125.
[2]Indicates that a Family Plan is available.
[3]Indicates that all rooms are air-conditioned.

Leisure Time Program

With approximately 12,000 persons expected to be in attendance in Honolulu, we suggest that advance reservations for these events will offer a considerable convenience due to limited capacities, as compared to arranging such activities after your arrival in Honolulu. Based on receipt of the form below, each event will be reserved in advance and tickets will be mailed to you upon receipt of payment. Complete the form below and mail together with your check in the appropriate amount payable to: "TRAVEL CONSULTANTS, INC." Please address the envelope to: "TRADE WIND TOURS; APA Coordinator," P.O. Box 2198, Honolulu, Hawaii 96805.

Position Statement on Peer Review in Psychiatry

This statement was approved by the Board of Trustees of the American Psychiatric Association at its December 8–9, 1972, meeting, upon recommendation of the Council on Mental Health Services. It was prepared by the Task Force on Peer Review in Psychiatry.[1]

> Medicine is not a science but a learned profession deeply rooted in a number of sciences and charged with the obligation to apply them for man's benefit. Traditionally this applying is made with compassion and in accord with a widely recognized moral and ethical code. Thus the responsibilities of medicine: to generate scientific knowledge and to teach it to others; to use the knowledge for the health of an individual or a whole community; and to judge the moral and ethical propriety of each medical act that directly affects another human being (1, p. 1).

PEER REVIEW is the pursuit and maintenance of this tradition. Unless physicians maintain open, frank, critical, and yet constructive self-examination, the review of medical procedures and practices will fall to the vast array of eager, but less qualified, public inspectors (2, 3): "What society [the public] has given society can also take away; namely . . . [medicine's] delegated privilege of regulating itself as a profession" (4).

There is a crisis in demands for quality and cost control in all phases of health care delivery. The crisis is particularly acute in relation to cost, quality, availability, and delivery of psychiatric services.

Concurrently a need is developing for effective psychiatric representation in the existing peer review process. The usual variations in accepted treatment practices that are known to occur in the course of individualized treatment programs are being brought into question by nonpsychiatric and at times nonmedical review. The clinician's flexibility in choosing treatment procedures requires effective peer representation on review committees in order to support continuing freedom and flexibility of practice.

The urgent need for positive, effective action on the part of organized psychiatry requires leadership by APA in promoting the development of peer review organizations in each district branch and at the national level. A mechanism for the implementation of this binary approach is described in the guidelines that appear later in this statement.

The goal of peer review is to *improve the quality of care through the continuing education of physicians, other providers, and patients in the methods for providing and for receiving better care at a minimum feasible cost consistent with high-quality care.* Therefore, peer review cannot be a static program with set standards. Although disciplinary measures or sanctions may be a *necessary* aspect of peer review, the *hope of effecting improved patient care lies in the educational thrust.*

A pervading concept among psychiatrists is that our current criteria for diagnosis, treatment, and determination of recovery vary so widely among individual practitioners and clinic and hospital groups that their standardization for general medical review seems impossible. Some psychiatrists recommend that peer review for psychiatric care be developed separately from the general medical review process. The philosophy of this approach is based on the principle that *quality health care for each individual patient is the primary concern.* The availability, utilization, cost, and quality of care *rendered by each individual practitioner can only be reviewed within the framework of quality health care for the total person.* Specialized approaches to health care, such as psychiatric diagnosis and treatment, are primarily the concern of the general medical community and should be reviewed at that level.

Specialty review is designed to assist, clarify, and represent a specialized viewpoint in the review process. The specialty review committee is a specialized resource available to the general medical review process and provides representation for the specialty practitioner whose services are being reviewed.

The concept of consumer review is being widely promoted both in Congress and throughout the country. *The peer review process is viewed as a basic strength that undergirds the structure of quality health care and that vitalizes the structure of the review process in such a manner that effective communication with consumer review is potentially available. There can be no effective consumer review without a readily available and effectively functioning peer review mechanism within the structure of the health care delivery system to maintain a live communication of knowledge, experience, and direction.*

IMPLEMENTATION OF GUIDELINES

Experience with the actual review process as it develops throughout the country will provide the best test of the capacity of psychiatrists to function within the mainstream of medicine in reviewing, as one phase of health care for our citizens, professional practice in the delivery of psychiatric services.

District branch peer review organizations should take an active and continuing role in consulting with the local medical peer review organization and with third-party carriers regarding the unique problems of standardizing criteria for review relating to all phases of psychiatric practice.

Continuing feedback to the district branch membership of peer review experience, decisions, and accompanying changes in practice is the basic, primary, and essential element in developing a viable peer review organization in a district branch.

Implementation of the recommendations of the APA Task Force on Peer Review is a practical necessity for effective peer review in the Association. There is a current need for *staff coordination* both to accumulate the rapidly developing information

[1] The task force included Rives Chalmers, M.D., chairman, Theodore W. Neumann, M.D., W.A. Cantrell, M.D., S.B. Black, M.D., W. Dever Kehne, M.D., Frank Sullivan, M.D., and Burton Goldstein, M.D.

from present district branch activity in peer review and to formalize relationships with third-party carriers such as Blue Cross, Blue Shield, commercial insurance companies, Medicaid, Medicare, CHAMPUS, the Federal Employees Health Benefits Program, etc.

To this end APA proposes a study, which, if funded, would cover six lines of activity: 1) study of the organization, functioning, and accomplishments of utilization review committees in private psychiatric hospitals and in general hospitals with psychiatric units. Findings from the hospitals would be checked against third-party payers in the area (Blue Cross plans, Medicare fiscal agents, etc.) as to the value of the hospital utilization committee in reviewing and controlling utilization; 2) study of the methods of utilization review of physicians' services now being used by or proposed by peer review committees of APA district branches; 3) visits to health insurance organizations to discuss problems of coverage of mental conditions and of methods and problems of utilization control; 4) continuation of work with the CHAMPUS program on methods and problems of utilization control; 5) study of problems of utilization control in the Canadian programs of medical insurance; and 6) continued efforts to generate data from Blue Cross and Blue Shield on federal employees in various geographical areas, showing the distribution of claimants who incur charges for psychiatric services under supplemental benefits by the number of visits and the amounts charged. Thus, it will be possible: 1) to monitor on a national basis the experience of institutional utilization committees and district branch peer review systems, 2) to gather the information essential to expand the guiding principles, and 3) to share information on solutions with other district branches encountering similar problems.

While recognizing that the district branch is the primary focus for the development of the continuing peer review process, it is believed that the major objectives of effective peer review organizations can be met only by the strong commitment of staff time and financial resources by the APA Central Office. The functions of the *Committee on Peer Review Organization will require specialized expertise.* There is at present urgent need for communicating experience among district branch peer review committees that already exist. There is also an urgent need for the establishment of effective liaison communication with national health insurance organizations, private insurance companies, and government-supported programs.

APA is already being called upon for advice regarding demonstrated examples of questionable practices. Advice is requested regarding the proper approach to dealing with these practices, as well as a demonstration of effective action on the part of American psychiatry to provide mechanisms of self-regulation to maintain high standards of psychiatric service.

Public confidence is basic to peer review. Our psychiatric and medical colleagues share our concern for an effectively functioning peer review process. Our attention to the maintenance of public confidence and our responsible awareness regarding the position of third-party payers, both tax-supported and privately funded, can establish a climate of cooperation in effecting the delivery of mental health services.

COST AND FUNDING

Aggressive promotion, coordination, and direction of the ongoing program of peer review may be an item of expense.

Planning and development in each district branch may demonstrate the need for some kind of ongoing staff service. Certainly, effective and continuing peer review will constitute a major demand on the professional time and energy of those members assigned to peer review organizations. *The educational objectives of peer review organizations will depend on attracting the services of psychiatrist members of the district branches who are most respected for their responsibility, fairness, and conscientious, ethical practice of our profession.* There are persons who already have demanding requirements within their work; provision for reasonable compensation for the professional time required of them will greatly strengthen the continuing quality and effectiveness of peer review organizations.

An early priority of each APA peer review committee should be the exploration of available financing and the development of a policy regarding the use of outside financing in program operation at the district branch and national levels. Psychiatry, the federal government, health insurers, and the consumer public should share in the cost of peer review programs.

GUIDELINES FOR PEER REVIEW IN PSYCHIATRY

Peer review is a mechanism of self-evaluation to maintain the quality of professional services. It is a means by which colleagues review, in a cooperative way, the quantity, quality, and cost of medical services. It thereby subsumes in its responsibility those functions which have been previously designated as claims review, utilization review, and quality review (medical audit) (2,5).

A binary program should be established by APA: 1) a regional peer review organization functioning within each district branch, and 2) a standing APA Committee on Peer Review Organization.

The Local Peer Review Organization

Each APA district branch should establish a peer review organization. It is noted that each district branch was, in fact, instructed by the Assembly of District Branches to submit its plan for peer review in writing by April 1, 1973. Further, the Assembly, following discussion by its area councils, stated that district branch peer review committees should be involved in the whole national mechanism of peer review and that peer review and continuing education are inexorably connected and should be considered as such for planning purposes. Each district branch, therefore, is expected to have a peer review organization. Such an organization should be made up of at least three knowledgeable members who represent varied experiences and approaches to the practice of psychiatry. The general membership should participate as broadly as possible in the process of selecting peer review committees, whether by appointment or by election. To assure a balance between continuity of experience and diversity of representation it is recommended that terms of services on the committee be staggered and that some limitation be placed on reappointment.

Provision should be made for an addition to the district branch or society by-laws that authorizes the peer review organization to function as a consultant to all interested parties regarding questions of fees, utilization, and quality of care related to the practice of psychiatry. Each organization should make its presence known to the appropriate APA area council, the state medical society, and APA at large.

Peer review organizations will have two functions: 1) as a specialty consultant peer review organization to the broader medical society peer review mechanism (stressing the continuing primary affiliation of psychiatry and medicine), and 2) as the

regional extension of APA's Committee on Peer Review Organization.

If the affiliate state, county, or district medical society has not yet established a peer review mechanism, the psychiatric peer review organization should take the initiative in activating such a mechanism, using as guidelines this document, those provided by the American Medical Association (6), and those of the American Society of Internal Medicine (7). Such a program should be designed to meet the specific needs of the geographical area and should generally provide for the following:

1. A well-defined and broadly publicized input mechanism should be available to physicians, care recipients, and interested third parties on all questions relating to physician-generated services.

2. Such an input mechanism should be the initial review organization, whose function would be to assemble necessary information from all involved parties.

3. The problem should then be presented to a multispecialty state, county, or district medical committee, whose charge would be to investigate, consider, and decide the issue. This decision should be forwarded, within a specified period, through the input organization to all involved parties.

4. The psychiatric peer review organization, as well as organizations representing the other medical specialties, should be available as a consultant to the aforementioned medical society organizations. They should also be available to provide expert advice to all interested parties on matters involving the respective specialty practice.

5. A well-defined appeals procedure should be established so that disagreement over decisions can be submitted to a multispecialty appeals organization and, as may be found necessary on occasion, through the highest medical authority within the region to the appropriate judicial court.

6. Specific legal safeguards should be established as an integral feature of the peer review mechanism (5, 6):

Confidentiality. The process of peer review should be conducted in such a manner that the individual (agency) whose services are being reviewed, and the involved recipient of care, have full protection of their rights to confidentiality. Under no circumstances should the data be duplicated and recorded elsewhere or made available to groups that are not connected with the treatment situation. The data should be used only to facilitate the treatment process (8).

Immunity from litigation. Physicians participating in the organizations should be provided with adequate legal protection against suits instituted by participants who are dissatisfied with the review process or decision. An opinion should be obtained from competent legal counsel in each state concerning the liability of physicians serving on these committees (9).

Protection from discovery. The decisions and records of the organization's proceedings should be adequately safeguarded so that they cannot be used against either the members of the organization or the physician (agency) whose services are being reviewed.

7. Review procedures should be standardized, guidelines should be developed, and policy manuals should be established and made available to the providers of service and third-party carriers (6, 7, 10). It is believed that this standardization of procedures and placing the decision-making responsibility within the purview of a multispecialty medical society organization will increase the objectivity of the peer review mechanism.

The APA Committee on Peer Review Organization

Purpose and Organization. The maturation of the local peer review organizations and the success of a meaningful and comprehensive peer review mechanism will depend on the development of three major programs that are integrated on the national and local levels: 1) an automated system for the collection, identification, dissemination, and storage of data, with a broadly available retrieval system (6, 7); 2) a research structure to provide exploration into problem areas as they are delineated: and 3) an educational program designed to effectively return accumulated information to the physician, the recipient of care, and third-party carriers (11).

It is envisaged that these programs fall within the purview of a Committee on Peer Review Organization that would be established by APA. Members of this committee should include psychiatrists who are well versed in data collection, research, and postgraduate education, as well as psychiatrists who are actively engaged in the various clinical applications of psychiatry.

The development of an automated system for data collection is planned as a phase to follow the research exploration of problem areas as they develop. The research studies, when funded, should serve as a monitoring mechanism in collecting difficult case examples for definitive study that may in turn lead to the formulation of disorder-oriented guidelines to quality treatment. It is noted that the APA Task Force on Peer Review suggests a single committee on peer review organizations to accomplish these objectives (data collection, research, and postgraduate education), but since they are quite different problems, it will remain for the Reference Committee of the Board of Trustees to study the recommendations carefully and to consider other options in order to realize their essential goals.

Through the above programs, the committee will strive to expand the expertise of the local peer review organization while depending on it for data collection, collaboration in designated research projects, and carrying out the eventual educational projects.

Broadening peer review to include assessment of the complete spectrum of physician-generated psychiatric care must initially be limited in scope, entering first those areas which render themselves most readily to definition and measurement, but rapidly expanding as experience is gained and as operational techniques are perfected.

Major Objectives. The major objectives of the Committee on Peer Review Organization follow:

- Education of the physician: Psychiatrists, like most practicing physicians, rarely communicate with each other regarding the day-to-day realities of practice experiences. The process of peer review will become an effective mechanism for communicating standards of quality, availability and utilization of services, and usual concepts of fees prevailing in the medical community. Communications regarding actual practice will provide a new and significant dimension of continuing educational experience for all parties involved in medical care and in methods of improving the quality of care.

- Evaluation of quality: It is within this area that continuing feedback through a viable and accepted educational program will determine the usefulness of any information gathered. Without the return of information to the provider of psychiatric care there can be no expectation of change. Consideration must be given not only to the evaluation of an educational device, but also to the study of a system revision that will lend itself to measurement, evaluation, and follow-up (12). The attempt to define the level of patient care and the effectiveness of such care must

be based on a system of record keeping that lends itself to audit (13–18).

Once such a base has been established the quality of psychiatric care may then be divided into three major areas for study and elaboration—structure, process, and outcome of treatment (19). *Structure* would include clarifying the qualifications of psychiatrists and paramedical personnel, working together or separately, and defining the terms and treatment modalities (with guidelines of usual patterns, structure, setting, duration, frequency, etc.). *Process* evaluation would involve assessing the practice of psychiatry through comparisons of observed behavior (empirical quality standards based on actual practice) or through sampled medical records with predetermined standards (normative quality standards based on textbooks, psychiatric records, etc.) (12–15, 19). The evaluation of *outcome* would take place at at least three levels: 1) the effectiveness of treatment by an individual or of a specific modality through medical audit, 2) the changes in patient care following dissemination of information to physicians through a well-organized patient-oriented educational program, and 3) a continuing evaluative program measuring the effectiveness of peer review/educational impact.

• Evaluation of cost: Information is already available through various third-party payers as to the general fee norms for various treatment modalities within geographical areas. These data should be available at both the local and national levels and, specifically, to those physicians falling outside the norm. Further study should attempt to establish explanations for variations in charges; these should be conveyed to the care recipient and third-party carriers.

• Evaluation of quantity/utilization (11): In this area significant information exists through hospital studies, insurance carriers, governmental agencies, community mental health agencies, and the like (6, 10, 20). This information must be integrated by and accessible to the peer review mechanism before further needs in this area can be determined.

Consideration of the availability of care should include an evaluation of the difficulties encountered by patients attempting to enter the mental health care system, the shortages of psychiatrists and paramedical personnel, and the lack of suitable patient care facilities (6). Information should be gathered regarding the distribution of services by psychiatrists, clinics, and other agencies caring for various demographic groups.

Data should be accumulated regarding the use of a psychiatrist's time, i.e., the hours devoted to patient care, administration, teaching, and supervision. An evaluation of psychiatrists' time in caring for patients must also eventually deal with effective utilization relative to the needs of the patient population. Consideration should be given to therapeutic approaches that shorten treatment time and duration, as well as to methods that increase psychiatrist/patient ratios (e.g., group therapy, use of paramedical personnel, educational programs for nonpsychiatric physicians) without sacrificing the effectiveness or the quality of care. Further, studies should appraise the utilization of psychiatrists' time in "elective" psychotherapy as opposed to treating the functionally impaired patient; guidelines will be needed to establish such a distinction (21). Effective utilization could be further aided by the establishment of guidelines for the functional determination of: 1) the need for treatment, 2) the most appropriate treatment for the specific disability, 3) the projected length of treatment and treatment goals, 4) spot evaluation during the course of treatment, and 5) response to treatment and follow-up of treatment effects(22).

Recommendations for desirable changes should be developed and communicated to the profession, public, and appropriate private and governmental agencies. Recommendations should be made to the public concerning how to obtain psychiatric care when problems of availability occur.

CONCLUSIONS

For a comprehensive peer review mechanism to develop within the specialty of psychiatry there should be a binary program: 1) the consultant role of the local psychiatric society peer review committees that function as part of the related medical society peer review mechanism and are available to physicians, patients, and third parties on all questions relating to the practice of psychiatry; and 2) a collaborative program, established by an APA Committee on Peer Review Organization and the local peer review committees, to actively study the cost, quantity, and quality of psychiatric practice through an evolving system of data collection, research programs, and a viable, acceptable educational program.

Position Statement on Psychiatrists' Relationships with Nonmedical Mental Health Professionals

This statement was approved by the Board of Trustees of the American Psychiatric Association at its December 8–9, 1972, meeting, upon recommendation of the Task Force on Interprofessional Relations.[1]

WITHIN THE PAST 40 years there has been an increase in public awareness and interest in the field of mental health, as well as a growth of knowledge and services. This has brought about extensions and modifications in the entire pattern of mental health care. A significant accompaniment of these changes and this progress has been the increased participation of nonmedical professionals in the delivery of mental health services to the public.

HISTORICAL PERSPECTIVE

In the last decade of the nineteenth century, the development of psychoanalytic theory shifted the focus of psychiatric inquiry and practice from the organic concept of mental illness to an awareness of the important role played by dynamic psychological factors. This shift led away from largely biologic, nosologic, organic, and symptomatic therapies and custodial care toward an effort to understand and treat the intrapsychic factors contributing to mental illness.

Later insights sharpened awareness of the role of social and cultural factors in the development of mental illness and in its prevention and treatment. Mental hygiene centers, developed in the 1920s and 1930s, employed various health professionals in a "team" approach, and "talking therapy" gained momentum. World War II brought great demands for treatment of psychiatric casualties. After the war, hospitals began to augment their psychiatric staffs by employing other physicians and nonmedical professionals in treatment programs.

Since the 1940s, the "shock" therapies, psychotropic drugs, and the open hospital concept have made possible the more rapid discharge of patients from mental hospitals. Many could be treated without hospitalization or for briefer periods of hospitalization, or in institutions and facilities closer to their homes and families. There has been a significant increase in psychiatrists in private practice. Psychiatric services have been established in hundreds of general hospitals, and the total number of patients treated has increased greatly in a few decades. A significant reduction of resident patients in mental hospitals has occurred each year since 1956. Mental health centers have been expanded, and outpatient follow-up centers and, most recently, a sizable number of comprehensive community health centers have been developed.

The concept of mental illness has been broadened from one in which psychiatry was concerned almost exclusively with psychotic patients (who represented a small percent of the population) to one in which the emphasis has become the commitment of the community's total mental health resources to serving and maintaining the mental health needs of the entire population.

Additional innovations have included day and night hospitals, group psychotherapy, case finding, mobile clinics, "outreach" approaches, behavioral and family therapy, and emphasis on preventive programs, all of which supplement and expand the skills and techniques of diagnosis, treatment, and rehabilitation.

These developments were accompanied by significant innovative legislation. Since 1942 Congress has passed the Vocational Rehabilitation Act, the National Mental Health Act, the act creating the National Institute of Mental Health, the Community Mental Health Centers Act, and acts providing for the Medicare and Medicaid programs. Not only have manpower and treatment facilities been improved by this legislation, but a shift in funding from largely state and private sources to federal and third-party funds has also resulted. Under the emerging concept of the right to treatment, public opinion now appears to support the establishment of new programs for the treatment of alcoholism, drug abuse, mental retardation, and geriatric problems, as well as the involvement of psychiatry in helping reduce crime and violence.

Psychiatry today has changed to new, creative, and even radical theoretical and technical approaches, including innovations in means of delivery of services to supplement those practices which have already proven effective.

The Emerging Role of the Nonmedical Mental Health Professional

Expanded training facilities for psychiatrists initiated by medical schools, public and private hospitals, and government and other agencies have not been able to fully meet the increased demand for skilled manpower. Furthermore, future needs are likely to continue to tax all existing facilities and may even require the creation of new types of institutions and facilities to bridge the gap between supply and demand.

Nonpsychiatric physicians, psychologists, social workers, and nurses have become part of the mental health team; they have made increasingly important contributions. To these must be added the special contributions of others such as occupational therapists, recreational therapists, special educators, chaplains, probation officers, vocational, educational, pastoral, and marital counselors, and all others who are employed in the vast mental health care enterprise.

New roles are being added to existing professions and new groups are emerging such as counselors, assistants, technicians, associates, program graduates, and indigenous helpers in mental health. Nor should we overlook the contributions of legal

[1] The task force includes William W. Zeller, M.D., chairman, Robert S. McKnight, M.D., Robert H. Thrasher, M.D., Abraham N. Franzblau, M.D., Alexander Levine, M.D., George E. Williams, M.D., and Donald F. Moore, M.D.

counsels, cost accountants, statisticians, dieticians, legislators, politicians, sociologists, and others.

The Changing Role of the Psychiatrist

Traditionally, the psychiatrist has been viewed by the public and by himself as the primary professional in the field of mental health. Rapid sociological change as well as excessive demands upon his time and energies for the delivery of mental health services have placed upon him additional roles and functions. He is no longer asked to treat only mental illness in all of its medical aspects; he is also called upon to give expert opinion and advice on a variety of social and community problems, which, by traditional training and experience, he may or may not be familiar with or prepared for.

These additional responsibilities have challenged the traditional role of the psychiatrist as well as the nature of his practice of psychiatry. This, along with the changing roles of the other professions, has resulted in considerable role blurring, which is one of the problems besetting the mental health field.

The Unique Role and Function of a Psychiatrist

The psychiatrist's role and function still remain that of a physician especially trained to administer to the needs of patients suffering from nervous or mental disorders.

The psychiatrist-to-be attends college, generally for four years, majoring in the physical and behavioral sciences, often including psychology and sociology and other liberal arts courses; he graduates with a bachelor's degree.

In the four years [2] of medical school training that follow, his studies embrace such basic sciences as biochemistry, anatomy, pharmacology, and physiology as well as clinical training and experience in surgery, internal medicine, pediatrics, gynecology and obstetrics, neurology, developmental psychology, psychiatry, and other areas of medical practice. He participates as a physician in the entire cycle of human life, suffering, and experience, from prenatal care to death. These are the minimum essentials that prepare him to treat and diagnose human illness—physical, psychological, and emotional—and qualify him for an M.D. degree.

Many physicians then serve as interns in an accredited general hospital. This, for the young physician, is an intensive, full-time working experience with patients; he functions as their physician under the supervision of more experienced colleagues. Subsequently he must pass rigorous examinations in order to become a licensed physician and practice medicine. These examinations are conducted by state medical boards that are accredited on a state or national level.

To become a specialist in psychiatry, the physician must engage in hospital training at a university medical center or an accredited teaching hospital, medical clinic, or other accredited teaching facility, where he serves as a resident psychiatrist for three years. The accredited training facilities for psychiatrists are in turn subjected to periodic review of their standards and procedures by the highest authorities of the profession.

To qualify as a Diplomate in Psychiatry, the candidate must in addition have at least two years of practical experience before becoming eligible to take the written and oral examinations administered by the American Board of Psychiatry and Neurology.

[2] A number of six-year programs combine the college degree and the M.D. degree.

Also, during his entire professional career the psychiatrist is subject to peer review to achieve and maintain staff privileges in the hospitals in which he practices. He is also accountable to the state and local medical societies and state licensure authorities as well as to the ethics committees of the American Psychiatric Association and its district branches.

The psychological and physical components of an illness are intertwined; at any point in the disease process, psychological symptoms may give rise to, substitute for, or run concurrently with physical symptoms; the reverse may also occur. The ability to deal effectively with this phenomenon is an important skill in which the psychiatrist is trained and which influences patient-therapist interaction and the outcome of treatment. His medical training and experience also qualify the psychiatrist to bring to bear upon the process of differential diagnosis not only interviewing techniques, history taking, and the physical examination, but also the findings of other medical examinations including physical, neurological, laboratory, and X-ray. In addition he is trained to recognize the various interpersonal social factors that may cause, influence, or modify emotional or mental disorders.

If hospitalization is required, the psychiatrist as a physician is authorized to admit and discharge patients. He also has the training and experience to select from the entire armamentarium of medical, surgical, and psychiatric modalities a treatment plan appropriate to the particular patient, and he is not limited to the various forms of psychotherapy.

Furthermore, the psychiatrist has the specialized skills and knowledge necessary for the conduct of meaningful and productive research into the origins of mental illness in collaboration with research scientists from other fields, and for making significant contributions to other mental health research.

Interprofessional Relationships

Recent developments in the field of mental health care have created problems for many people—professionals, consumers (patients, clients, parishioners, etc.), governmental regulative agencies, insurance companies, and others involved and responsible for third-party payments and the delivery of mental health services.

Most persons in the professions of psychiatry, psychology, social work, nursing, occupational therapy, vocational rehabilitation, and lately other professions such as religion and the law, have cooperated and collaborated in a positive way for many years. By and large, mental health professionals have worked well together in mental hospitals, psychiatric departments of general hospitals, clinics, mental retardation centers, correctional facilities, rehabilitation and aftercare organizations, schools, social agencies, religious institutions, courts, industry, and, in many instances, private practice. Psychiatry today regards favorably the growing trend to work collaboratively with other physicians and nonmedical professionals in the delivery of many mental health services.

Historically, as psychiatry shifted from care to treatment, the needs for services outran the availability of psychiatric manpower, and psychiatrists began to look to other professionals for assistance. The help of these other professionals was enlisted to provide specialized skills and services in such areas as clinical testing, casework, administration, and basic research; many were also trained to do psychotherapy under psychiatric supervision. The "team approach" care provided by physicians and associated professionals became standard.

Some nonmedical professionals then elected to leave institutional settings and move out into private practice to do clinical testing, casework, and various forms of psychotherapy. In time,

the nonmedical professionals set up training institutions under their own auspices to teach psychotherapy. As the number of these grew, they sought to advance their professional interests and their practices. Clinical psychologists have been especially active in promoting legislation for licensure and certification; such legislation has been passed in almost all of the states. In a number of states, similar legislation has been passed for other professionals.

As the number of independent professional practitioners increased, concern about the maintenance of quality of services to the public was shared by psychiatrists, other physicians, and many leaders of the nonmedical professions. The public has few ways of ascertaining the competence of those who offer them services, except through the safeguards of professional licensing or certifying laws. It is important that all such safeguards be valid if the interests of the public are to be protected.

Some Problems

In the mind of persons seeking help there is confusion over who is best qualified to do psychotherapy. The psychiatric skills in "talking therapy" have a relationship to those utilized by practitioners in other helping professions. Consider the clergyman who counsels a disturbed or distraught parishioner, the lawyer who seeks to reconcile a couple on the verge of divorce, the social worker who strives to knit a family that is shattering, the teacher who assists the potential of a handicapped pupil to blossom; even the trusted family doctor who receives confidences from a troubled patient. There is some similarity between psychotherapy and counseling, consoling, advising, and even just listening sympathetically. But there are also enormous differences; they are by no means interchangeable. The psychiatrist is not only trained to do psychotherapy, he is also trained to make a differential diagnosis, to prescribe medication or somatic therapy, and, if need be, to hospitalize a patient for treatment. The kind of help that each professional offers is dependent upon the background, training, professional attitudes, knowledge, and special skills of the particular professional involved.

Another major problem that the health professions face today is meeting the challenge of a society that has come to the realization that access to health care is a human right in a just society. In these times when health, education, and welfare are considered to be rights for every person, psychiatry by itself can shoulder only a limited portion of this responsibility. The help and cooperation of all professions is essential.

Distribution of health care to all segments of society presents great problems that must be resolved. The Medicare and Medicaid systems for providing funds to pay for health care for the elderly and for certain disadvantaged groups have met part of the problem, but by no means all. Pressure is mounting to provide more care for much larger segments of the population. However, existing mechanisms are proving too inefficient and too costly to allow greater coverage, and even the present coverage is in jeopardy for financial reasons. At the same time, current major mechanisms for financing health care are being challenged as subject to abuse.

There undoubtedly will be much more discussion as to who should participate in health care programs and which groups of professionals will be paid under them. Many of the health care bills currently before Congress do not at this time include provisions for psychiatric services. The psychiatric profession and other mental health professions undoubtedly share concern about this particular aspect of national health care programs.

Active issues such as which professions should have primacy in delivering mental health care, who should be head of the mental health team,[3] who is best qualified to do psychotherapy, or who should be paid by governmental or insurance agencies deserve further attention. However, there should no longer be divisive wedges among professions striving toward the common goal of providing a high-quality, comprehensive, and coordinated system of health care equally accessible to all.

Many questions arise out of the growing borders between the professions involved in mental health care. The American Psychiatric Association has attempted in the document that follows to suggest some relevant and reasonable guidelines for its own membership and for consideration by related nonmedical professions and the public.

OBJECTIVES OF THE PROFESSION OF PSYCHIATRY

The American Psychiatric Association, in its Constitution, states the following to be its objectives:

> (a) to improve the treatment, rehabilitation, and care of the mentally ill, the mentally retarded, and the emotionally disturbed; (b) to promote research, professional education in psychiatry and allied fields, and the prevention of psychiatric disability; (c) to advance the standards of all psychiatric services and facilities; (d) to foster the cooperation of all who are concerned with the medical, psychological, social, and legal aspects of mental health and illness; and (e) to make psychiatric knowledge available to other practitioners of medicine, to scientists in other fields of knowledge, and to the public.

To focus these constitutional objectives on interprofessional relationships, we believe the major responsibilities of psychiatry to the public, to its own members, and to other professions can be better understood by further clarification and delineation.

MAJOR RESPONSIBILITIES OF PSYCHIATRY

Psychiatry's Responsibility to the Public

Public education. To inform the public as to the unique and special services that the psychiatrist, as a physician especially trained in the promotion of mental health and the treatment and prevention of mental and emotional disorders, can render to them. Certain facts should be emphasized and distinguished, namely:

- Psychiatrists are physicians, whereas other mental health professionals are not.
- As such they are trained to make a differential diagnosis between the physical and the emotional aspects of disorders, which are frequently intertwined.
- The treatment of psychiatric disorders involves the use of a wide spectrum of modalities such as psychotherapy, medications, other somatic treatment, and at times hospitalization.
- Delay in the use of such other treatment modalities may have serious or even fatal consequences for some patients.

[3] This issue becomes especially important when it is essential that psychiatry recognize the important contributions that other nonmedical professions have made or are making.

Active participation. To participate actively in developing programs and procedures for the delivery of the highest quality of psychiatric services to all groups of people, determined only by what is appropriate to the needs of each.

Rights of consumers. To recognize the right of recipients of mental health services to be informed regarding the competencies and limitations of all who offer their services and to choose which person, profession, or agency they wish to consult in seeking help.

Development of better laws. To participate in the development of laws to protect the public as recipients of mental health services.

Psychiatry's Responsibility to Members of Its Own Profession

Definition of function. To clarify and define the field of practice, area of special competence, and appropriate spheres of activity of the psychiatric profession.

Education and training. To promote programs of the highest quality for the education and training in psychiatry of medical students, psychiatric residents, and nonpsychiatric physicans, and for the continuing education of psychiatrists to assure the maintenance of high levels of competence in the profession.

Standards of service. To establish and maintain high standards of medical (including psychiatric) patient care.

Ethics. To assure the maintenance of high ethical standards within the psychiatric profession by setting effective methods and techniques of internal control.

Utilization of manpower. To achieve the maximal recruitment and utilization of psychiatric manpower.

Research. To support, encourage, and implement research in psychiatry in both basic and clinical sciences.

Prevention. To work toward the prevention as well as the alleviation of mental illness.

Liaison. To encourage effective liaison among psychiatry, other medical specialties, and nonmedical professionals.

Psychiatry's Responsibilities to Other Professions

Definition and delineation of interprofessional relationships. To recognize that every professional group has a right to establish and maintain its identity and independence by defining its own functions and areas of competence, setting up its own educational and training programs, and establishing its own standards of service. As a responsibility to the public, society may recognize the profession and set up such controls as it may deem necessary. No profession should attempt to define the functions and responsibilities of any other profession.

Education and Training. The responsibilities of psychiatry include the following:

- To inform members of other professions regarding training, experience, areas of special competence, and appropriate spheres of activity of the psychiatrist.
- To assist when invited in the education and training of other professionals in any areas in which psychiatry has a contribution to make, and on subjects within the scope of those other professions as they may be legally defined.
- To encourage and foster ongoing mutual education programs through joint meetings, seminars, and workshops with other professional organizations.

Standards of service. To work in close cooperation with other professionals when requested to do so in order to utilize the expertise of all available professions in the provision of high standards of service to the public.

Ethics. To recognize that the establishment and maintenance of codes of ethics are an internal responsibility of each profession and that complaints against other professionals should be directed to the responsible authorities of the profession concerned.

Manpower, research, and prevention. To collaborate with other professions in these important areas.

Liaison responsibilities. To recognize such responsibilities, the American Psychiatric Association offers the following guidelines in reference to the settings and situations in which problems in interprofessional relations often arise:

- In medical settings: The American Psychiatric Association, in concurrence with the American Hospital Association, endorses the principle of appointing members of other professions such as nurses, dentists, social workers, sociologists, ministers, and psychologists to the staff of hospital and other facilities to bring to the treatment of patients their specialized knowledge, skill, and experience. In such a setting the physician-psychiatrist retains the primary medical responsibility, established by law and custom, for the admission, diagnosis, treatment, rehabilitation, and discharge of patients.
- In nonmedical settings: Psychiatrists function increasingly in many settings such as mental retardation centers, regular and special education schools, correctional institutions, social service agencies, and others that do not have a primarily medical orientation. A psychiatrist working as a consultant, supervisor, therapist, or administrative staff member in such a setting has essentially the same relationship to the organization as other professionals have in a medical setting. However, he must retain ultimate responsibility for the psychiatric and medical care of the patients or clients whom he serves.
- In office practice: The psychiatrist recognizes the special skills and competencies of other professionals and sends or refers people to them for appropriate services, based on the other professional's education, training, experience, competence, and reputation.
- Third-party payments: Psychiatry endorses payment under medical insurance plans such as Medicaid or Medicare to nonmedical health professionals when their services are rendered as part of a plan of treatment that is supervised and/or prescribed by a physician. However, professionals in various allied fields often elect to engage independently in health-related pratices in a nonmedical setting. A person should feel free to select the practitioner of his choice from among qualified professionals. If there is a public demand for health-related services that are not normally regarded as medical or offered as part of a total medical treatment program, insurance companies may offer insurance for such health-related services as they currently do for medical treatment. If the federal government wishes to provide publicly supported programs for such services, appropriate legislation will have to be passed.
- Legal responsibility: When psychiatrists extend their services to other health professionals in meaningful collaboration (which includes supervision of cases or participation in interdisciplinary teamwork), they are obliged to know about and to be willing to assume the established legal responsibilities involved.

CONCLUSIONS

The quality of the relationships among the helping professions will have great bearing upon the success or failure of the mental health programs now functioning or projected in the future. This position statement is offered to help psychiatrists, other physicians, and nonmedical health professionals to meet the obligations and fulfill the potentials of their interprofessional relations and to enhance public understanding.

Position Statement on Homicide Prevention

This statement was approved by the Board of Trustees of the American Psychiatric Association at its December 8–9, 1972, meeting, upon recommendation of the Assembly of District Branches.

IN VIEW OF the increasing violence in our society and the fact that homicide deaths are now a significant contributor to national death rates, comparable to a degree with suicide, war, and vehicle deaths, and

In view of the particular relationships of firearms to homicide and personal injury with the resultant threat to life and security, adding to the fears and stresses in a crowded urban society, and

In view of the peculiar nature of firearms, which are prone to misuse by those with impulsive, explosive, and paranoid personalities as well as by those with criminal propensities and others with defective ego control, and

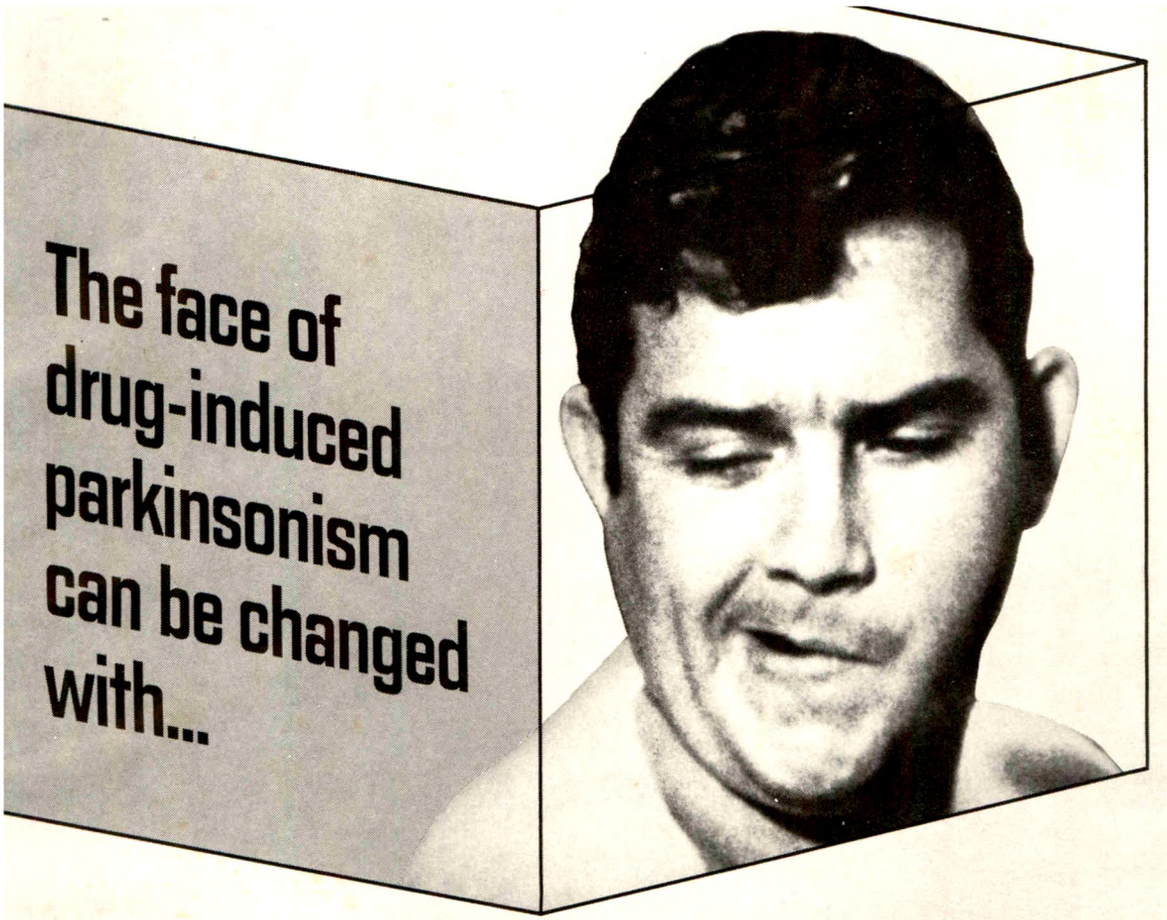
In view of the need to reinforce individual and group sanctions against the use of violence as a social instrument, behavioral mode, or adaptational pattern as psychiatrists have done with drug abuse, suicidal actions, and antisocial behavior,

BE IT RESOLVED that the American Psychiatric Association recommend that strong controls be placed on the availability of all types of guns and rifles, with particular consideration to a policy of confiscation of hand weapons, but with safeguards for the retention of appropriate weapons by police forces and others who have a clearly defined requirement for the retention of this class of firearms.

Position Statement on Involuntary Hospitalization of the Mentally Ill (Revised)

This statement was originally approved by the Board of Trustees of the American Psychiatric Association on March 3, 1972, upon recommendation of the Committee on Psychiatry and Law.[1] *It was revised by the Board of Trustees at its December 8–9, 1972, meeting, upon recommendation of the Assembly of District Branches. (The sole change consists of an addition to the paragraph numbered 3; the new material is indicated by italics.)*

THE AMERICAN PSYCHIATRIC ASSOCIATION is convinced that most persons who need hospitalization for mental illness can be and should be informally and voluntarily admitted to hospitals in the same manner that hospitalization is afforded for any other illness.



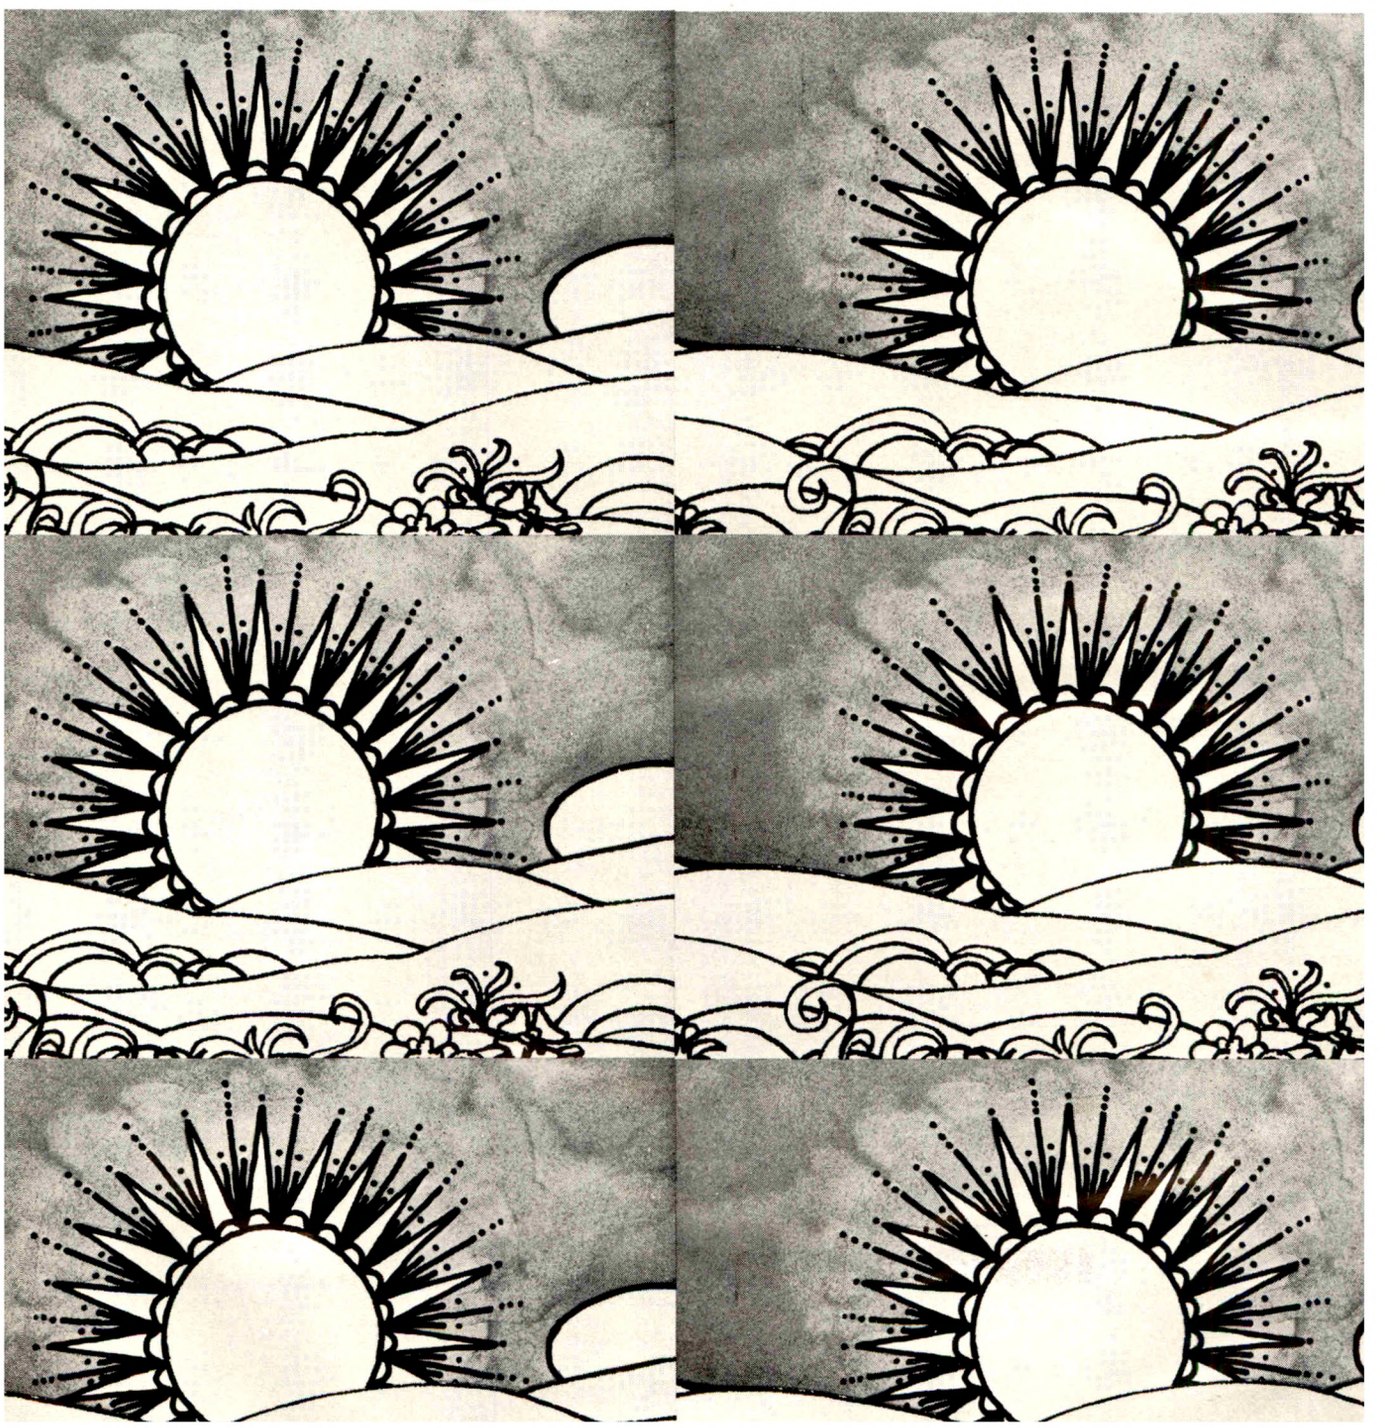
Moreover, modern concepts of psychiatric treatment emphasize the use of community-based outpatient facilities for the treatment and care of the mentally ill who voluntarily seek these services. Psychiatrists attempt to avoid hospitalization to every possible extent, although for some patients a period of hospitalization, usually brief, continues to be the indicated treatment.

Unfortunately, a small percentage of patients who need hospitalization are unable, because of their mental illness, to make a free and informed decision to hospitalize themselves. Their need for and right to treatment in a hospital cannot be ignored. In addition, public policy demands that some form of involuntary hospitalization be available for those mentally ill patients who constitute a danger either to themselves or to others. In such cases, it is a public responsibility to guarantee the right to treatment and to due process. This guarantee can have meaning and substance only if provision is made for proper judicial review, and for appropriate and adequate procedures, treatment facilities, and personnel.

Any form of involuntary hospitalization should provide full rights of due process: all of these rights should be guaranteed the patient regardless of the ability to pay for the services they may entail. It is suggested that these rights encompass the following provisions:

1. That a psychiatric examination and evaluation be made by the hospitalizing physician;
2. That the patient and other parties to the procedure have legal counsel available to them;
3. That the court, *or the jury when requested by the patient*, promptly determine the need for hospitalization, and in making such determination have available to it the results of an examination of the patient by one or more psychiatrists;
4. That, in addition, examination by one or more independent psychiatrists other than those appointed by the court be allowed the patient if he requests it;
5. That if, and after, the patient is hospitalized, frequent and periodic reports of his condition, treatment, and progress be made to the committing court or to its agency, to the patient's attorney, and to all of the examining physicians, and, further, that the responsibility for follow-up action on these reports be that of the agency attached to the committing court;
6. That the patient have the right to seek a judicial determination of the need for his continued hospitalization at reasonable intervals of time, and not less than every six months, that in such proceedings the patient be entitled to legal counsel and to examination by one or more independent psychiatrists, and that the burden of proof of the need for continued hospitalization rest with the responsible treatment authority or agency; and
7. That no patient be denied treatment because of administrative, judicial, or institutional delay.

[1] The committee includes Herbert E. Thomas, M.D., chairman, Stanley L. Portnow, M.D., Norman I. Barr, M.D., Herbert A. Raskin, M.D., G.J. Sarwer-Foner, M.D., and Paul R. Miller, M.D.; serving as consultants are Professor Henry H. Foster, Jr., and Ephraim Gomberg.



AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally: **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

The new-day constant for drug-induced parkinsonism:

ARTANE®
TRIHEXYPHENIDYL HCl

Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

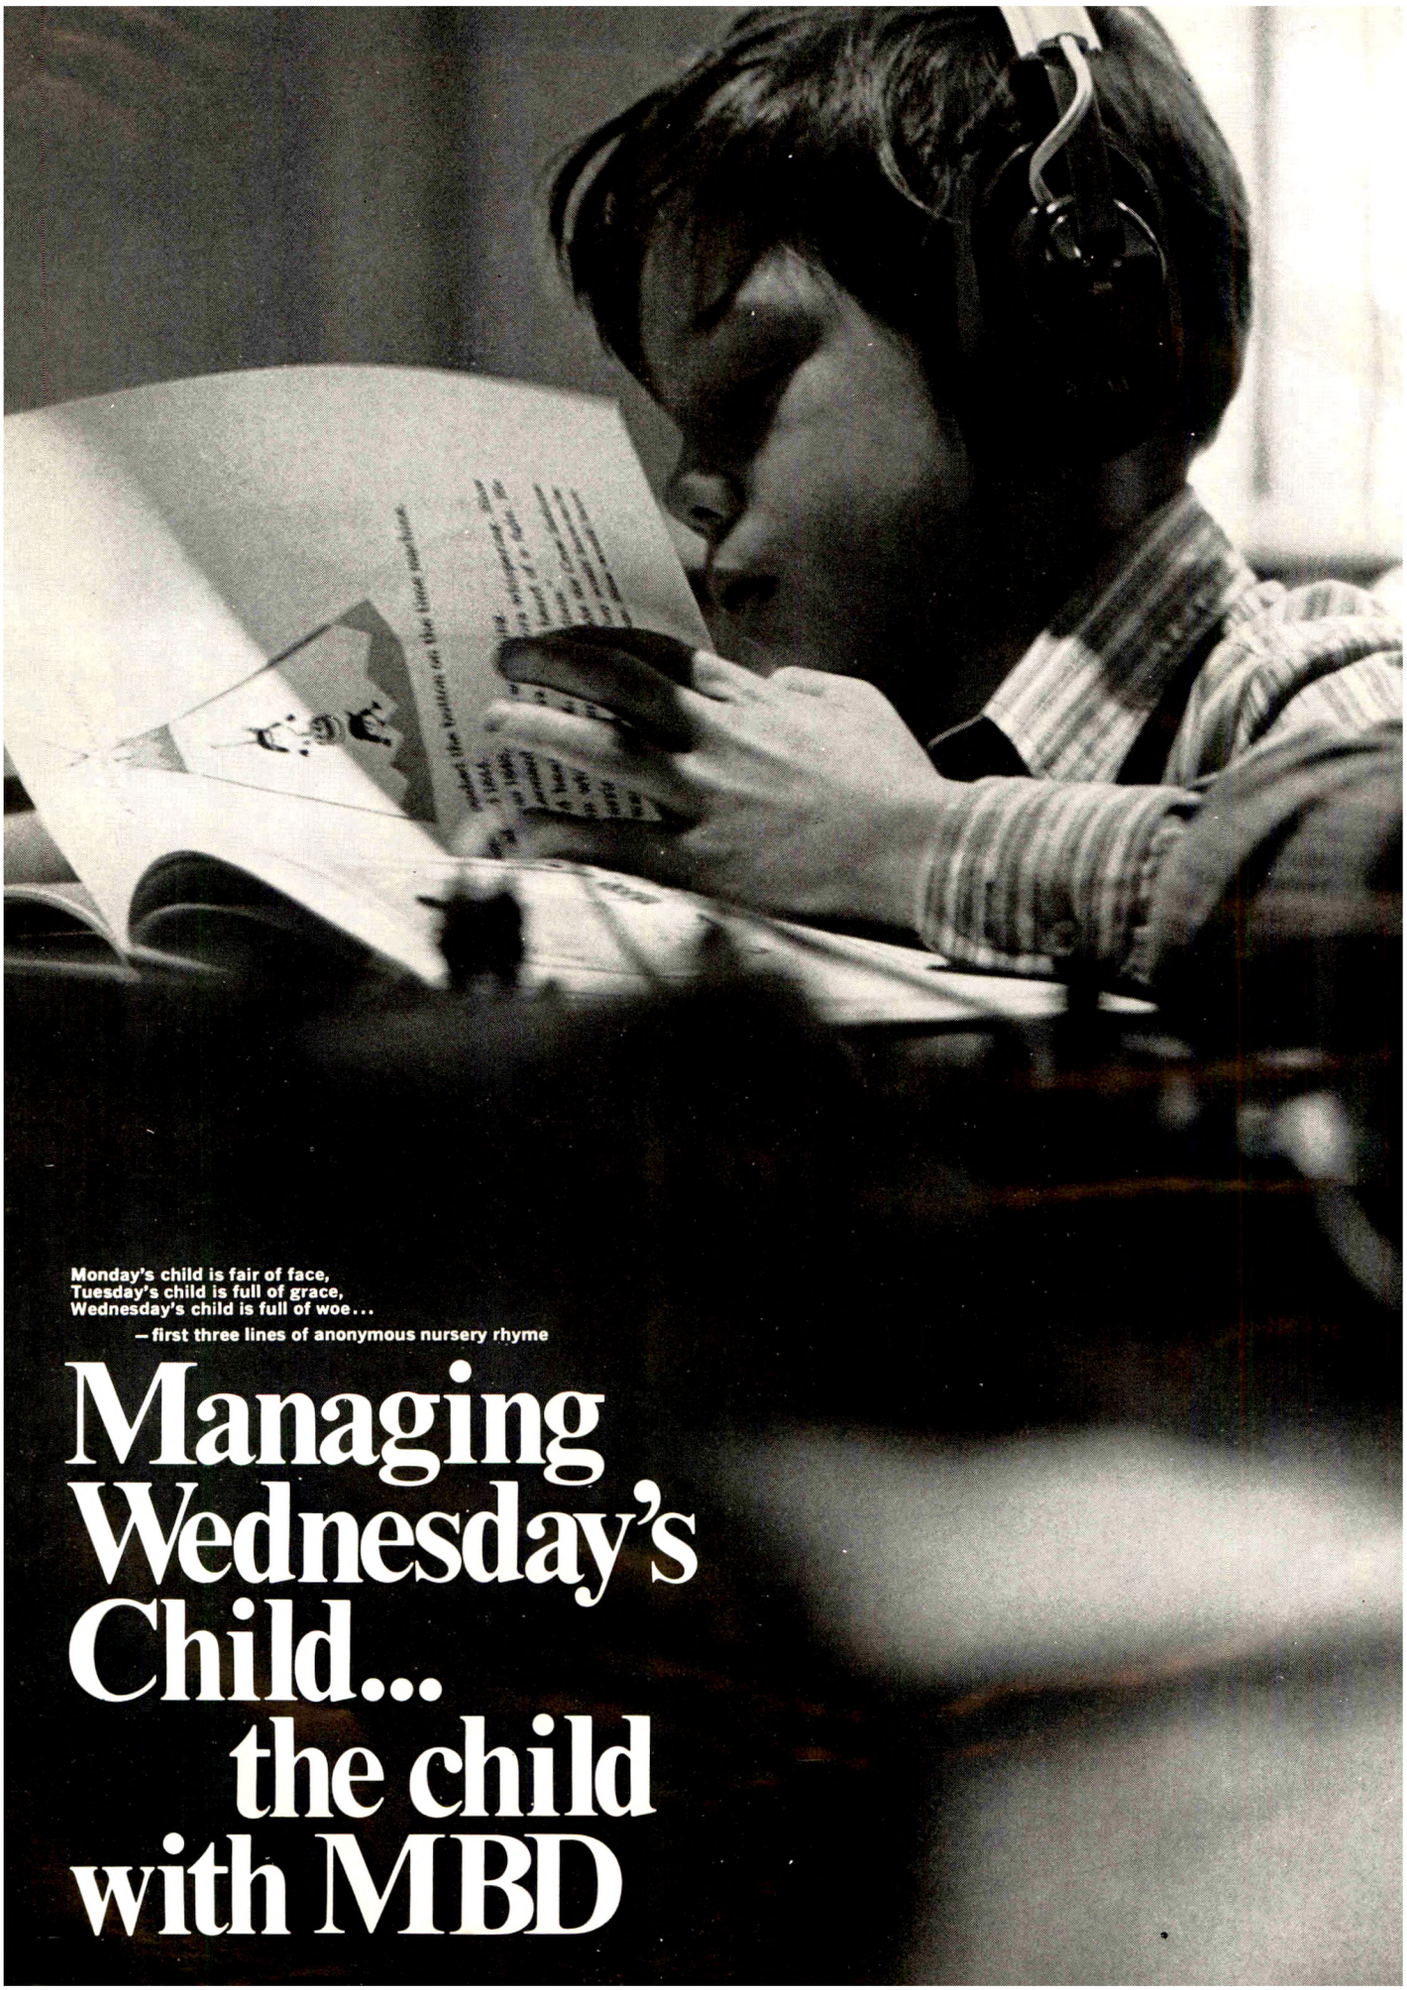
Tablets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

Tablets and Elixir Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

WARNING:
Patients to be treated should have a gonioscope evaluation and close monitoring of intraocular pressures at regular periodic intervals.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.



Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.

*This drug in sustained release form has been evaluated as probably effective. See Brief Summary.

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established. Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored. Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states. Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (eg, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

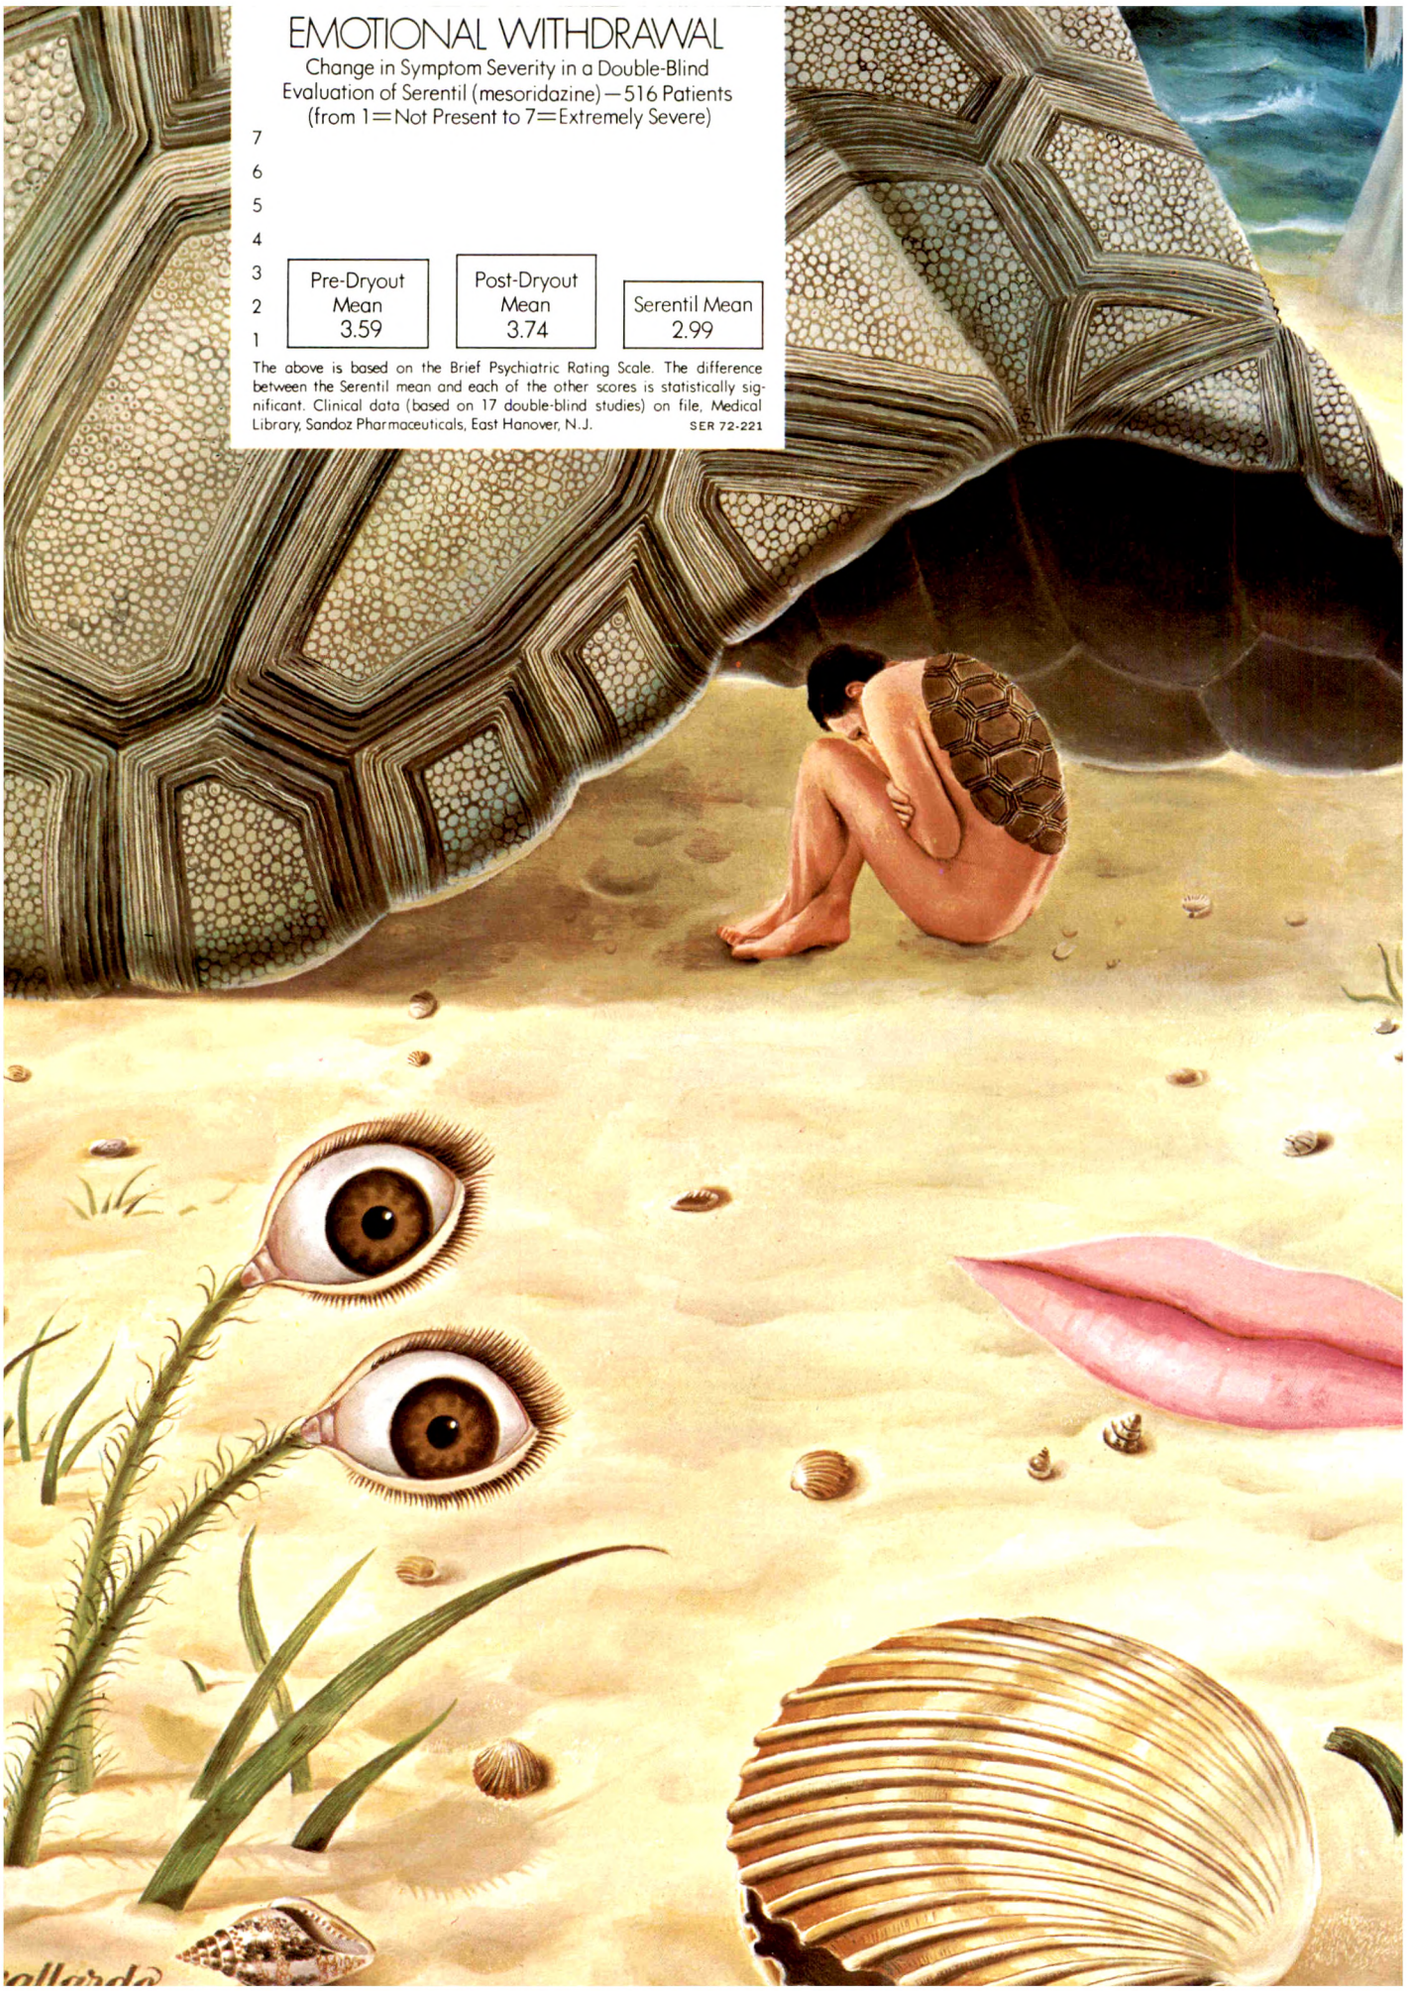
If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.



Consult complete product literature before prescribing.

SANDOZ

See next page for brief summary.

EMOTIONAL WITHDRAWAL
CONCEPTUAL DISORGANIZATION / ANXIETY
TENSION / HALLUCINATORY BEHAVIOR
SUSPICIOUSNESS / BLUNTED AFFECT

One or more of these symptoms in a schizophrenic is an indication for

Contraindications: Severe central nervous system depression, comatose states, hypersensitivity.

Warnings: Increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence, it should be given only when the anticipated benefits to be derived from treatment exceed the possible risks to mother and fetus. Use in children under 12 is not recommended. Phenothiazines are capable of potentiating central nervous system depressants as well as atropine and phosphorus insecticides.

Precautions: Ocular changes (seen with other phenothiazines) have not been seen with Serentil (mesoridazine). Because of possible hypotensive reactions, caution in parenteral use is required. Reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. Blood dyscrasia (seen with other phenothiazines) has occurred in a single case of transient granulocytopenia.

Adverse Reactions: Serentil (mesoridazine) has demonstrated a remarkably low incidence of adverse reactions when compared with other phenothiazine compounds. *Central Nervous System:* Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Endocrine System:* Inhibition of ejaculation and lactation have been noted rarely. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension, tachycardia, EKG changes.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. There is no evidence that these changes are precursors of any significant disturbance of cardiac rhythm. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia, behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

Dosage and Administration: ORAL: Should be adjusted to needs of the individual. Lowest effective dosage should always be used. When maximum response is achieved, dosage may be reduced gradually to maintenance level. *Schizophrenia:* For most patients, regardless of severity, starting dose of 50 mg. t.i.d. recommended. Usual optimum total daily dose range 100-400 mg. *Behavioral Problems in Mental Deficiency and Chronic Brain Syndrome:* For most patients starting dose of 25 mg. t.i.d. recommended. Usual optimum total daily dose range 75-300 mg. *Alcoholism:* For most patients usual starting dose is 25 mg. b.i.d. Usual optimum total daily dose range 50-200 mg. *Psychoneurotic Manifestations:* For most patients usual starting dose is 10 mg. t.i.d. Usual optimum total daily dose range 30-150 mg. INJECTABLE FORM: For situations in which an intramuscular form of medication is indicated. For most patients a starting dose of 25 mg. is recommended, to be repeated in 30-60 minutes if necessary. Usual optimum total daily dose range 25-200 mg.

Before prescribing, consult package circular.

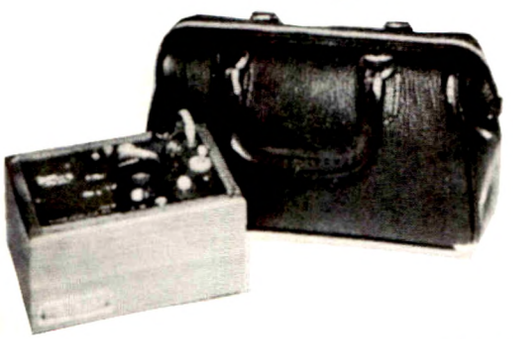
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

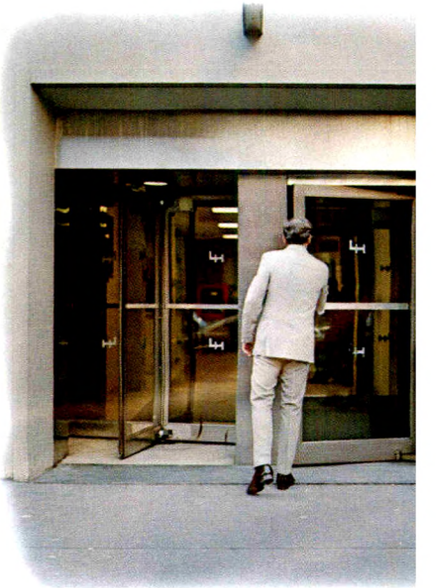
REUBEN REITER, Sc.D., INC. 187 Sylvan Ave., Leonia, N.J. 07605 — Tel. (201) 944-1211



The challenge: versatility

The stereotype image of "psychiatrist and couch" is an anachronism because today's psychiatrist is called on to diagnose and treat depression in a variety of clinical settings. And when an antidepressant medication is chosen, it must be as flexible and as adaptable as the physician prescribing it.

The psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL® (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

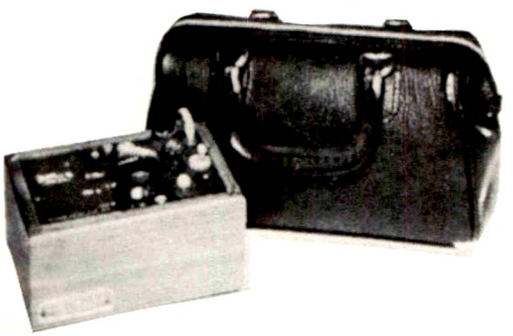
The general hospital today usually provides a psychiatric unit where depressed patients are treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models– **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS–THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives–patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes –a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II–The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

The challenge: versatility

The stereotype image of "psychiatrist and couch" is an anachronism because today's psychiatrist is called on to diagnose and treat depression in a variety of clinical settings. And when an antidepressant medication is chosen, it must be as flexible and as adaptable as the physician prescribing it.

The psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL® (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

The general hospital today usually provides a psychiatric unit where depressed patients are treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic, where follow-up treatment may be necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital, severely depressed patients present challenges for psychiatrist and staff alike. Here, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

The community mental health center, a remarkable innovation in the field of modern psychiatry, offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

helps open many doors

For a brief summary of prescribing information, please see following page.

MSD
MERCK
SHARP &
DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction or for patients under 12 years of age.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: The intravenous administration of 1–3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

New APA publications—

HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST

AUTHORS: Louis S. Reed, Ph.D., Evelyn S. Myers, Patricia L. Scheidemandel

Those who hedge on granting the mentally ill adequate and equitable coverage under any national health insurance system have done so mainly on the ground that it would bankrupt the system. This book shows that this is not so. The most comprehensive study of the utilization and cost of care for mental disorders under health insurance ever undertaken, it gives facts and figures on more than 40 private health insurance plans or organizations, Medicare, other public programs in this country, and Canadian programs of hospital and medical service insurance. A wealth of data on inpatient care, in-hospital physicians' services, and ambulatory care is provided.

You've talked...
you've listened...
but here she is again.

Looks like chronic anxiety.* Looks like a case for

Stelazine®

brand of **trifluoperazine HCl 2 mg. tablets**

For mildly anxious patients, your reassurance and some friendly advice will often carry the patient through the anxious episode.

But for chronic neurotic anxiety—the patient for whom anxiety is a constant part of life—medication may be required.

'Stelazine' can provide incisive control of anxiety, let the patient function more normally, and make her more receptive to your counsel.

* 'Stelazine' has been evaluated as possibly effective for this indication. See Brief Summary.

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

* **Indications**

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

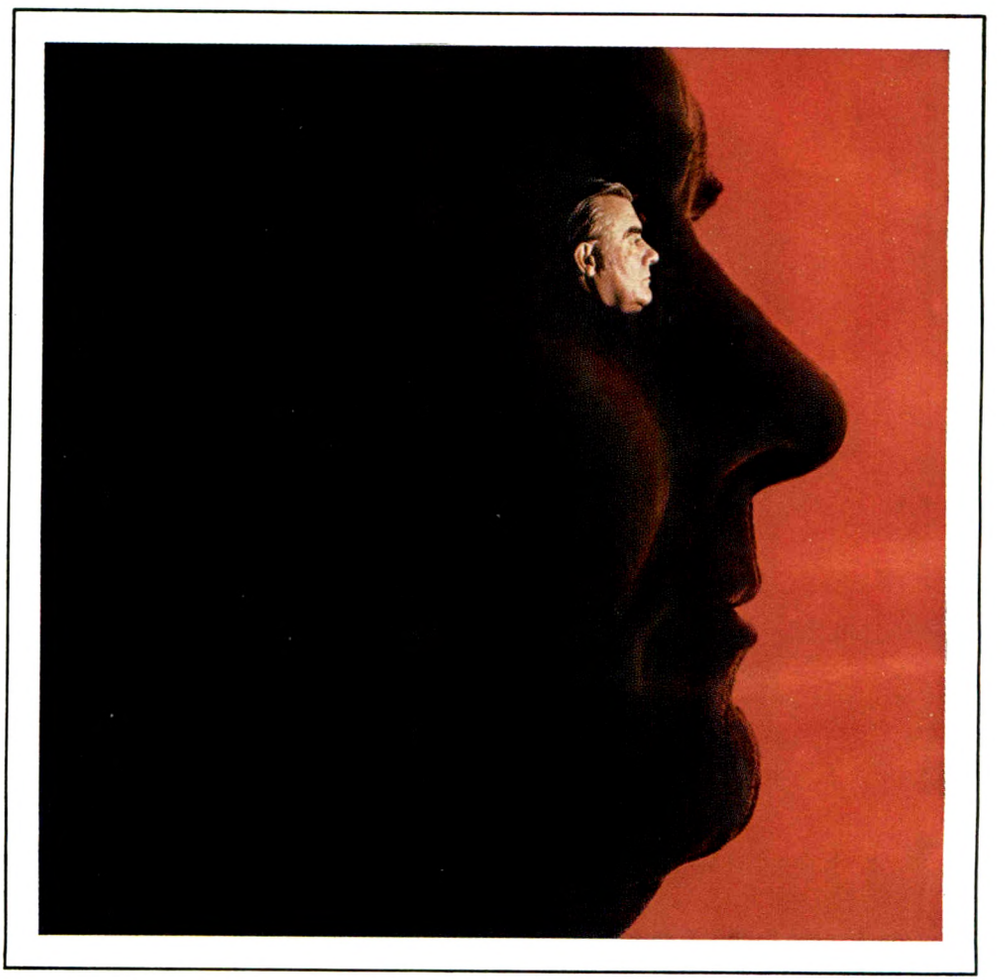
Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.



Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; Injection, 2 mg./ml.; and Concentrate, 10 mg./ml.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, under Stelazine® trademark license from Smith Kline & French Laboratories, Philadelphia, Pa.

BASIC ANXIETIES OF TODAY'S NEUROTIC PATIENT

The Inadequate Self

Low Self-Esteem... High Levels of Anxiety

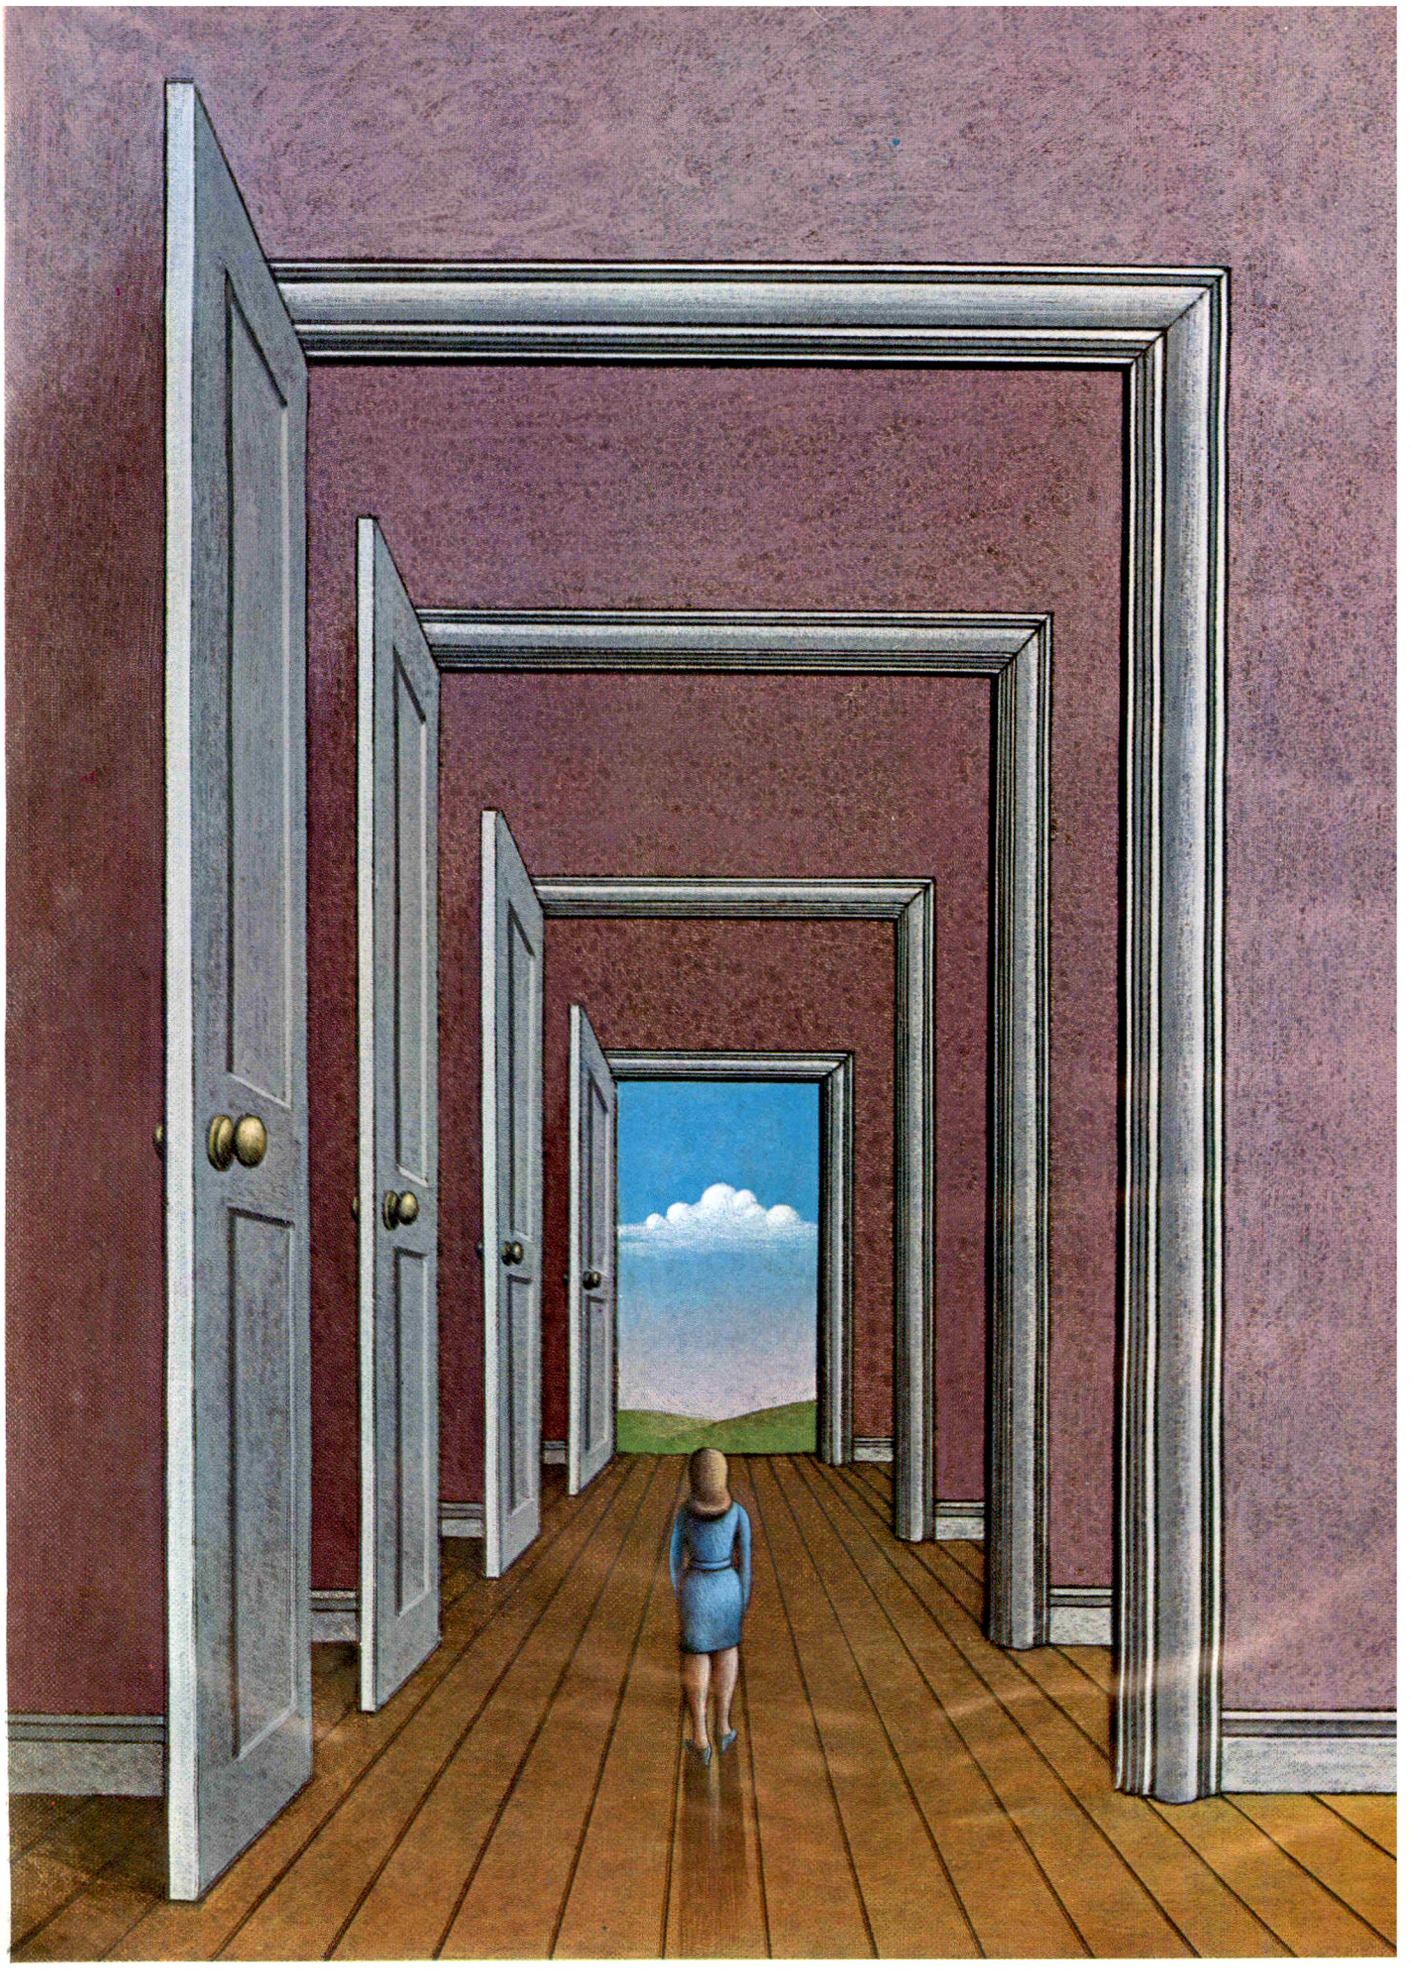
When the neurotic patient thinks of himself—and he tends to be excessively introspective—his thoughts often represent an extreme self-judgment, a condemning of himself. Characteristically, the neurotic is controlled by self-defining patterns of thoughts inadequately (or pathologically) developed in childhood. (In many cases, his negative self-evaluation stems from the internalization of early parental contempt.) Now, as an adult, he still sees himself as puny, weak, ineffectual, even worthless. Moreover, he lives in a constantly changing, extraordinarily complex and dehumanizing society which, unlike the societies of more stable eras, tends to *deepen* the individual's feelings of inadequacy and helplessness—his inability to cope with stress and to make decisions.

Because the neurotic patient's self-image may be poor, he takes great pains to conceal his presumed inadequacies from others, and their evaluations of his behavior can assume enormous importance. Furthermore, any real, or imagined, disapproval from others tends to induce disproportionately high levels of immobilizing anxiety.

In such cases, the neurotic patient may find himself in a peculiar kind of trap: severe anxiety—with its handicapping effect on both performance and concentration—may reinforce his sense of inadequacy and thus help perpetuate his already ingrained, habitual low self-esteem.

Librium (chlordiazepoxide HCl) In Today's Psychiatric Practice

In many such cases—when the patient's anxiety is, in the therapist's opinion, severely distressing and disabling—Librium (chlordiazepoxide HCl) often becomes a highly useful adjunct to psychotherapy. A dependable, effective antianxiety agent, Librium generally helps keep the neurotic patient's anxiety at tolerable levels, until such medication is no longer required. In addition, the calming influence of Librium may help the patient remain significantly less tense and apprehensive *between* counseling sessions—and may thus help to restore effective performance. In general use, the most common side effects reported have been drowsiness, ataxia and confusion, particularly in the elderly and debilitated. (See summary of prescribing information.)



Librium®
(chlordiazepoxide HCl) 10-mg, 25-mg capsules up to 100 mg daily in severe anxiety

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

ROCHE

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

A HEAD START FOR THE CLINICALLY DEPRESSED PATIENT.

All tricyclic antidepressants take from one to four weeks before optimal antidepressant effect is seen.

Sinequan (doxepin HCl)—the newest tricyclic antidepressant—is no exception.

But, in that waiting period, Sinequan offers the clinically depressed patient both:

prompt sedative activity to begin relieving the sleep disturbances often characteristic of depression, and

marked antianxiety activity to help relieve the apprehension, tension, worry and fear that usually accompany depression.

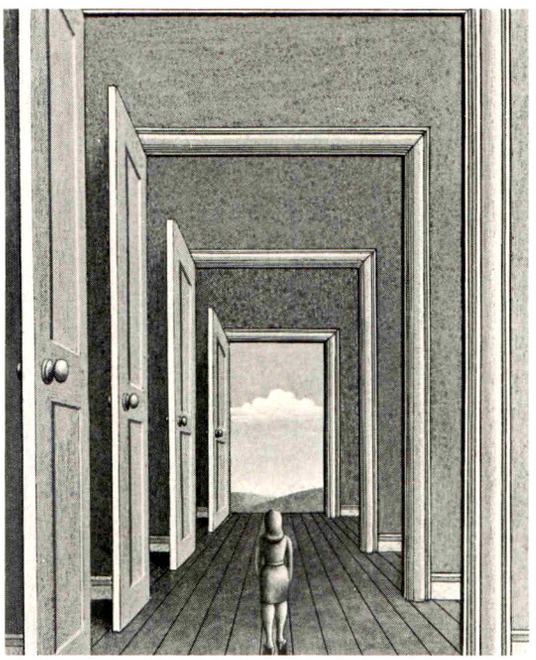
Further, the incidence of cardiovascular side effects with Sinequan is relatively low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) And Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses.

Prompt sedative activity. Marked antianxiety activity. Low incidence of cardiovascular side effects.

It's a head start for the clinically depressed patient.

THE NEWEST TRICYCLIC ANTIDEPRESSANT— WITH DIFFERENCES YOU CAN SEE.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules



Pfizer LABORATORIES DIVISION
PFIZER INC.

©1973, PFIZER INC.

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules

THE NEWEST TRICYCLIC ANTIDEPRESSANT—WITH DIFFERENCES YOU CAN SEE.

BRIEF SUMMARY
Sinequan® (doxepin HCl) **Capsules**

Contraindications. Sinequan (doxepin HCl) is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan (doxepin HCl) is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan (doxepin HCl) has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan (doxepin HCl) in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan (doxepin HCl). The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan (doxepin HCl) has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan (doxepin HCl), however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan (doxepin HCl) can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan (doxepin HCl) does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

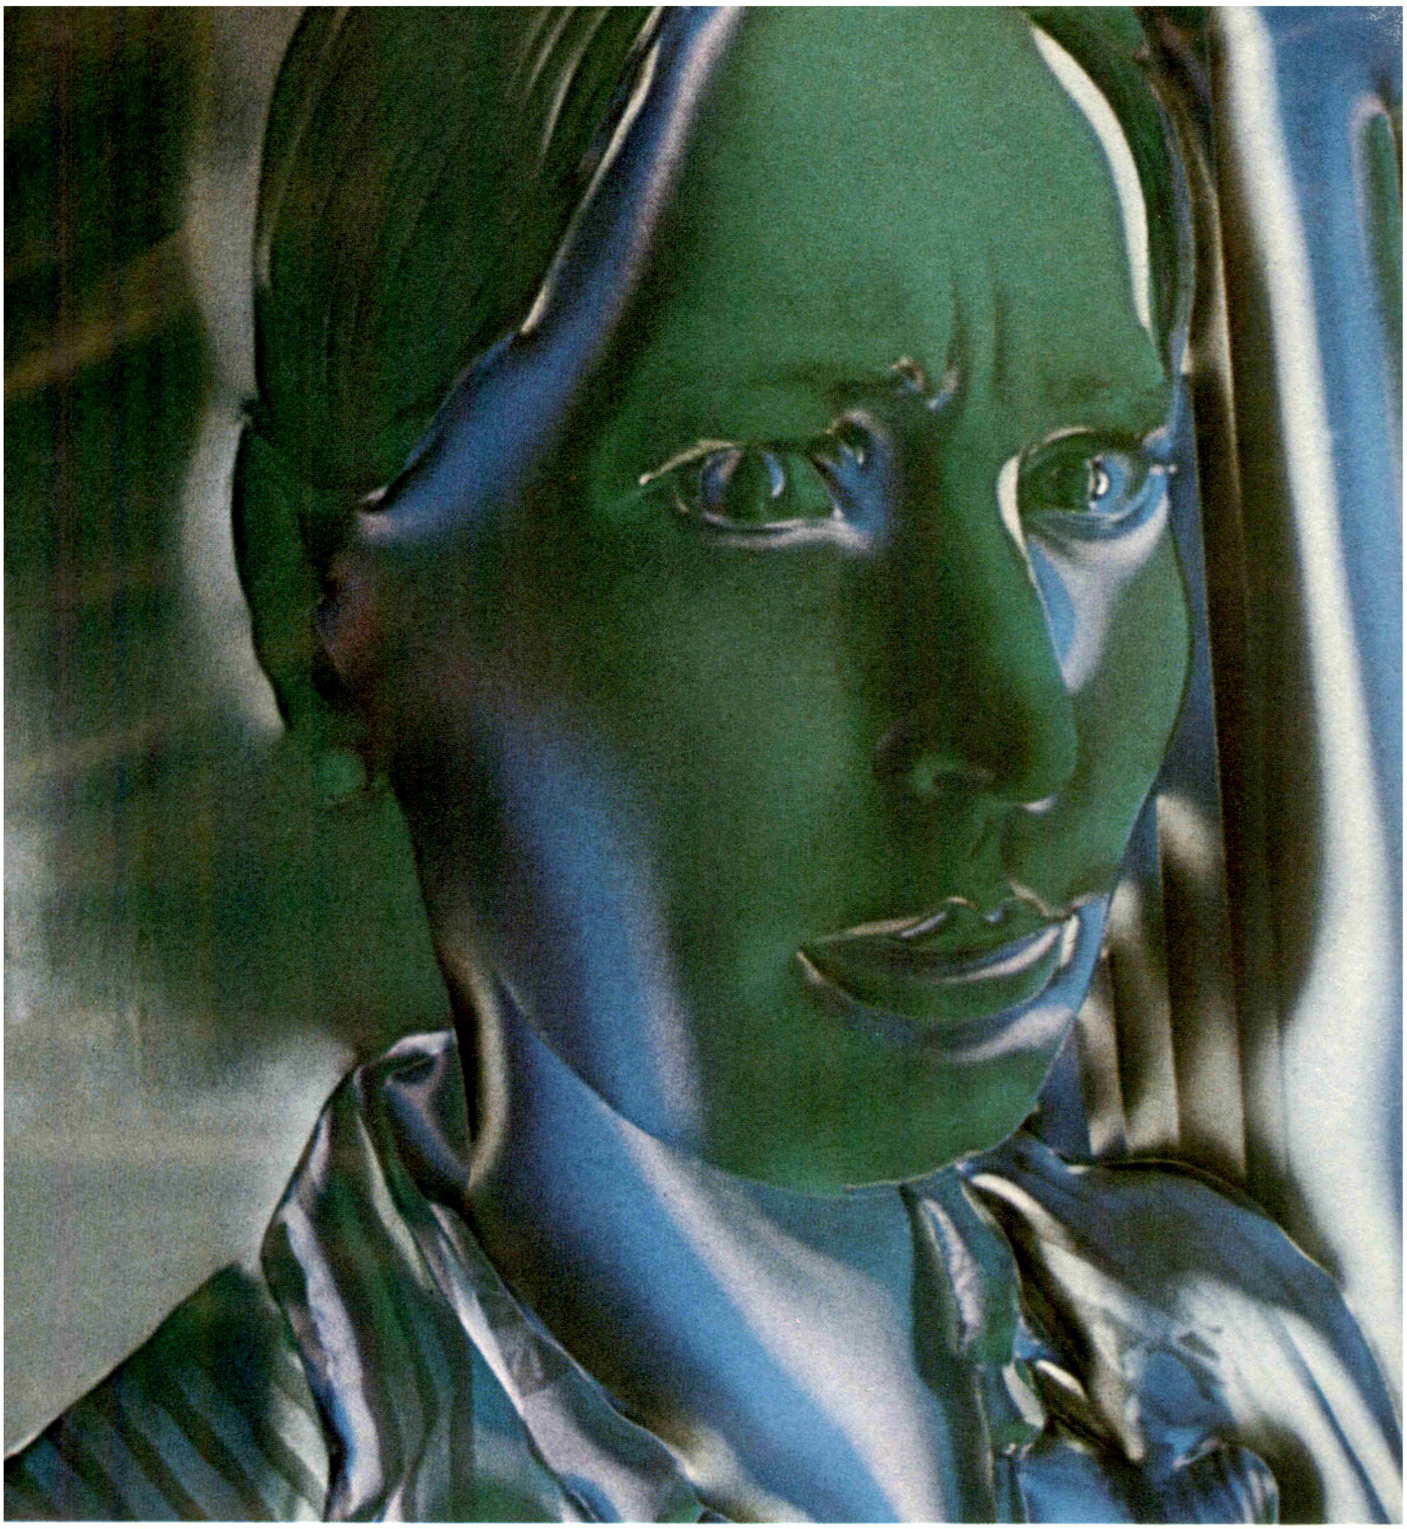
Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.



In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan (doxepin HCl) is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., and 50 mg. of doxepin in bottles of 100 and 1000.

More detailed professional information available on request.

Pfizer **LABORATORIES DIVISION**
PFIZER INC.

Suspicious and hostile?...Or accessible?

While psychotic symptoms remain acute, the barrier between you and the overly suspicious, hostile patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

accessibility often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

Haldol®
(HALOPERIDOL)

a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

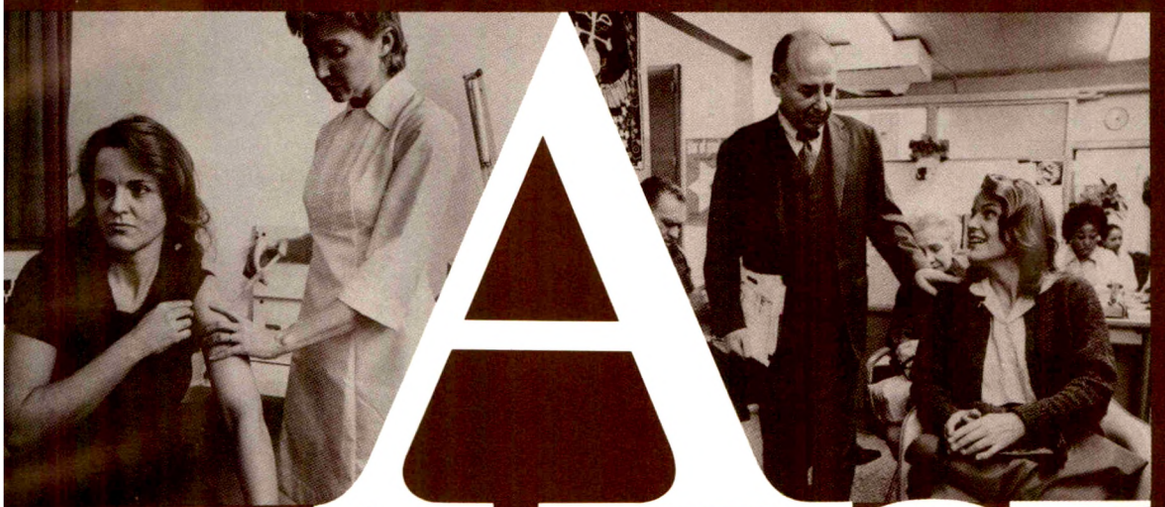
Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General—Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

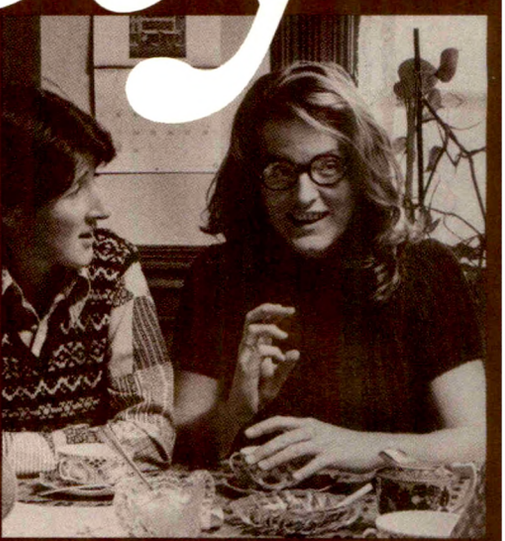
If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.



Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.



IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

For schizophrenic patients...

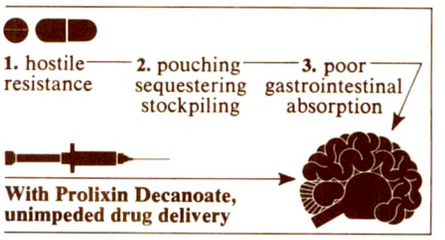
A way out:

...that helps keep them out

Controlled Drug Delivery

with new

PROLIXIN® DECANOATE



(FLUPHENAZINE DECANOATE INJECTION

Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer with an average duration of effect of about 2 weeks

Controlled drug delivery — a revolution in patient management

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) HELPS ASSURE EFFECTIVE, UNHINDERED MEDICATION

Controlled drug delivery is *physician*-controlled delivery, an effective prophylactic maneuver against disruption of therapy—one of the most common causes of psychotic relapse. Is the patient taking his medication? You know because you administer it or direct others to. Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.

In most patients, symptomatology is controlled by Prolixin Decanoate for periods of two weeks with a single injection. Sequestered medication and similar problems associated with oral therapy are not encountered. Nor does the patient risk drug loss through severe diarrhea or poor gastrointestinal absorption. Prolixin Decanoate keeps the patient medicated...helps make him more amenable to the entire treatment program and improves his chances for rehabilitation and discharge.

The outpatient is vulnerable to the dictates of his own poor judgment. Deluded by a sense of well-being, he may question the need for medication. Family and friends often give him misleading advice. Oral therapy in such a patient encourages missed doses. Medication with Prolixin Decanoate (Fluphenazine Decanoate Injection) helps assure drug delivery when required and in the dosage prescribed. It helps keep the outpatient out.

Missed doses.

FOUR REASONS FOR READMISSION...

For brief summary, see last page of this presentation.

OLIXIN® DECANOATE
uphenazine Decanoate Injection)
SURES ECONOMIC DRUG
:LIVERY...LESS FREQUENT
)SING THAN WITH ORAL
[ERAPY

Controlled drug delivery brings cost therapy down with less hospitaliza-ı, less nursing time, less frequent ıing. Low annual dosage means less t for the hospital, for the patient's ıily, and for the community. It ans a minimum of drug holidays to)id long-term complications, with ir confusing schedules for patient l family.

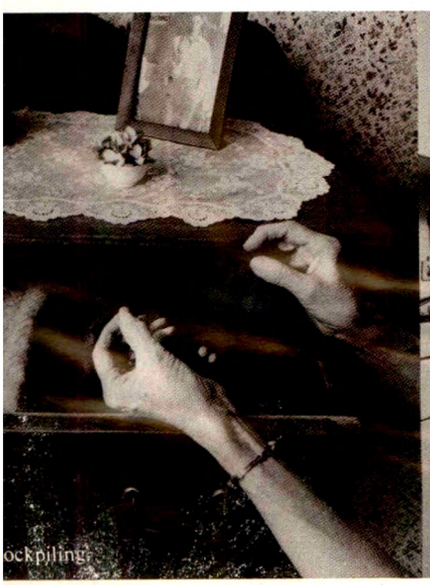
ntrolled drug delivery — evolution in the treatment of the ıizophrenic patient

OLIXIN® DECANOATE
uphenazine Decanoate Injection)
:LPS ENHANCE LIKELIHOOD
' DISCHARGE

Optimally, the mental hospital)uld be a rehabilitating bridge be-:en life before and life after custo-ıl care. Prolixin Decanoate often)rtens that bridge because getting the)atient out is frequently a matter of :eping him medicated. And 1 injec-n of Prolixin Decanoate means ap-oximately 2 weeks of symptom ntrol. The importance of control by : physician with this injectable can seen in the fact that about 1 out of :ry 5 inpatients does not take his tab-s even when they are administered by nursing staff. With controlled drug delivery, lost or hidden doses are not a problem.

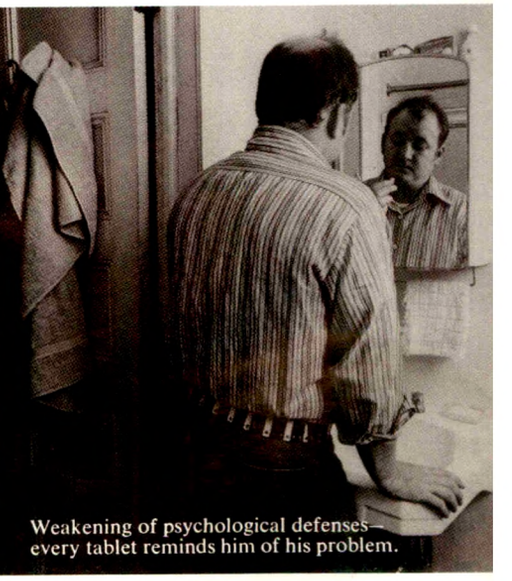
In one study,[1] 24 chronic long-term hospital patients were treated with Prolixin Decanoate in dosages of 12.5 mg. to 75 mg. given every 7 days to 3 weeks. Most of the patients received 25 to 50 mg. per injection. Of these, 13 were discharged after 6 months of treatment, 4 were considered dischargeable, and 7 did not improve. In 12 of the 24 patients who previously had been on different psychotropic drugs for periods of 4 to 96 weeks, improvement with Prolixin Decanoate (Fluphenazine Decanoate Injection) was observed in affect, volition, and higher mental functions. Dischargeability in these patients "may also have been enhanced because the staff, the patient, and the family were assured of an adequate and regular medication intake."[1]

Controlled drug delivery — a revolution in the care of the outpatient



PROLIXIN® DECANOATE
(Fluphenazine Decanoate Injection)
PROMOTES CONTINUITY OF MEDICATION WITH DIMINISHED LIKELIHOOD OF RELAPSE COMPARED WITH ORAL THERAPY

Success in rehabilitative areas like employment and social acceptance depends in large measure on adequate and continuing phenothiazine intake; success in family adjustment no less so. Short-acting medication is not the best path to such success. According to one report,[2] "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication." And McClellan and Cowan[3] state that a substantial number of patients taking antipsychotic drugs do so in amounts significantly less than those prescribed. Even once-daily administration does not solve the problem of poor home supervision or the patient's lack of insight into his condition.



Controlled drug delivery with Prolixin Decanoate (Fluphenazine Decanoate Injection) is an efficient route to continuity of medication, and therefore to long-term remission. For one thing there is less strain on the patient's often tenuous adjustment to family living. Since family members are not responsible for supervising the patient's medical needs, they tend to be more accepting, and better feeling is promoted merely because the controlled delivery regimen demonstrates that improvement is possible. Controlled drug delivery also strengthens the patient's psychological defenses. He is not reminded of his psychiatric illness by multiple daily doses.

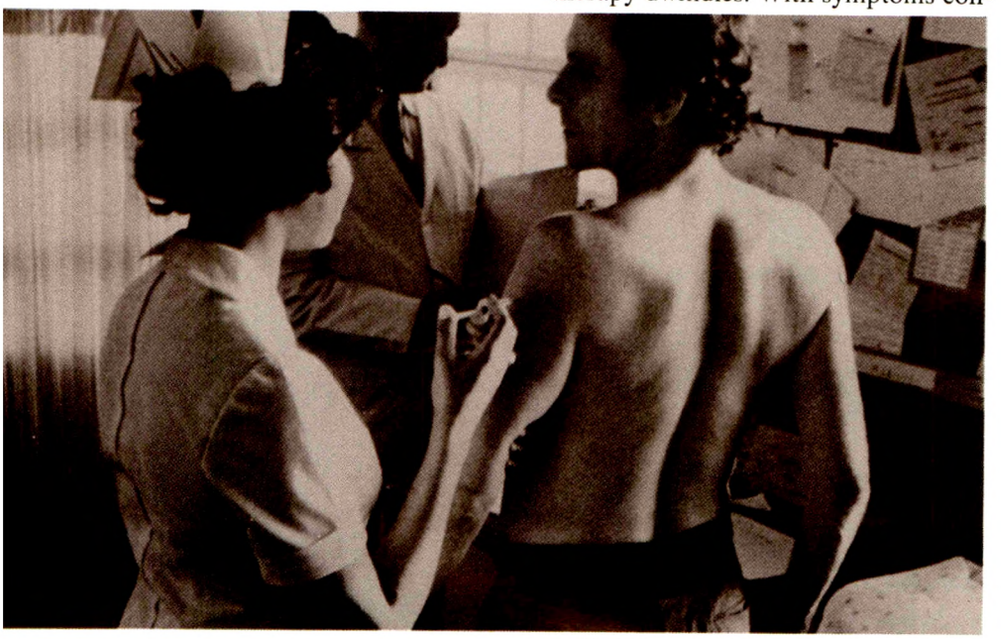
The same unique advantages of controlled drug delivery with Prolixin Decanoate that promote the discharge-

(Continued on following page)

ockpiling.

Misleading advice from family and friends.

Weakening of psychological defenses— every tablet reminds him of his problem.



)OD REASONS FOR CONTROLLED DRUG DELIVERY

(Continued from preceding page)
ability of the inpatient and help maintain him in the community are true for the patient who has never been hospitalized. It is just these advantages that will help the physician or psychiatrist keep him in the community without the need for custodial care.

Controlled drug delivery — a revolution in efficiency of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) SAVES TIME, REDUCES COST IN THE HOSPITAL, CLINIC, OFFICE

Controlled drug delivery saves time, reduces costs in the hospital. With Prolixin Decanoate there can be no palming, pouching, regurgitating. With Prolixin Decanoate resistance to therapy dwindles. With symptoms controlled, the patient is more manageable, more comfortable, more amenable to the total hospital treatment program. With Prolixin Decanoate only 1 dose visit every 1 to 3 weeks with an average of about 2 weeks is required.

Controlled drug delivery saves time, reduces costs in the clinic and office.

With Prolixin Decanoate less frequ dosing. With Prolixin Decanoate (phenazine Decanoate Injection) n patients report for their injections c once in every 2-week period.

Controlled Drug Delivery

in schizophrenia with new

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anti-cholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

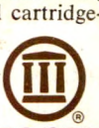
ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of anti-parkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage. A persistent and sometimes irreversible pseudo-parkinsonian syndrome may develop with chronic administration of phenothiazine compounds. Rhythmic, stereotyped dyskinetic involuntary movements, particularly of the face, mouth, tongue and jaw occur, and may be accompanied by choreiform movements of the limbs. The symptoms persist after drug withdrawal. Antiparkinsonian agents are seldom of benefit. The risk appears to be greatest in elderly females with organic brain damage receiving large and prolonged doses. Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.



Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

Supply: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

5 NEW BOOKS OF SPECIAL INTEREST IN PSYCHIATRY

☐ **ADDICTION: An Artificially Induced Drive** *by* **Nils Bejerot,** *Karolinska Institutet, Stockholm, Sweden. Foreword by* **S. S. B. Gilder.** Abuse of drugs may be a symptom of social or psychological maladjustment. Addiction is classified herein into single, epidemic, and endemic cases. Some principles of treatment and of attacking drug epidemics are discussed on the basis of these theories. Other important topics of interest are discussed. This text will be of special interest to those concerned with this problem. *'72, 96 pp., 8 il., 3 tables, $7.50*

☐ **RELIGIOUS EXPERIENCE: Its Nature and Function in the Human Psyche. The First John G. Finch Symposium on Psychology and Religion** *by* **Walter Houston Clark, H. Newton Malony, James Daane** *and* **Alan R. Tippett.** *Foreword by* **Lee Edward Travis.** The roots of religion are not in growths of church, belief, or ethics, but in religious experience. The text shows that properly directed, profound religious experiences are potent sources of personality change. References are made to case illustrations. *'72, 168 pp., 1 il., $7.95*

☐ **CRISIS CENTER/HOTLINE: A Guidebook to Beginning and Operating** *edited by* **Ursula Delworth, Edward H. Rudow** *and* **Janet Taub.** *All of Colorado State Univ., Fort Collins. Foreword by* **Western Morrill.** *(12 Contributors)* Presented in a general manner, providing useful information about the day-to-day operation of a crisis center. Insights and experiences by both professionals and volunteer students are included, thus providing a model for the inclusion of paraprofessionals in the mental health field. *'72, 160 pp., $9.75*

☐ **THE THEORY AND PRACTICE OF PSYCHOTHERAPY WITH SPECIFIC DISORDERS** *edited by* **Max Hammer,** *Univ. of Maine, Orono. (10 Contributors)* Provides psychotherapists with exposure to the newest and most effective approaches today. Case illustrations are amply and appropriately supplied. Areas rarely discussed in psychotherapy books are included. A chapter is devoted to establishing some basic criteria for an effective therapeutic process. Offers new interpretations and theoretical discussions. *'72, 464 pp., $16.75*

☐ **THE MECHANISMS OF CONDITIONED BEHAVIOR: A Critical Look at the Phenomena of Conditioning** *by* **Wanda Wyrwicka,** *Univ. of California, Los Angeles.* This study analyzes the well-known data as well as new findings in conditioning experiments and interprets them from a new point of view. The role of such factors in conditioning as time intervals, sequence of stimuli, permanent environmental features, and a possible mechanism of formation of the conditioned neural pattern are thoroughly discussed. *'72, 192 pp., 16 il., 2 tables, $11.50*

☐ **PRACTICAL PROBLEMS OF A PRIVATE PSYCHOTHERAPY PRACTICE** *compiled and edited by* **George D. Goldman** *and* **George Stricker,** *both of Adelphi Univ., Garden City, New York. (14 Contributors)* '72, 300 pp., 6 il., 3 tables, $11.50

☐ **MENTAL HEALTH SERVICES FOR THE MENTALLY RETARDED** *edited by* **Elias Katz,** *Univ. of California, San Francisco. (19 Contributors)* '72, 292 pp., 4 il., $12.75

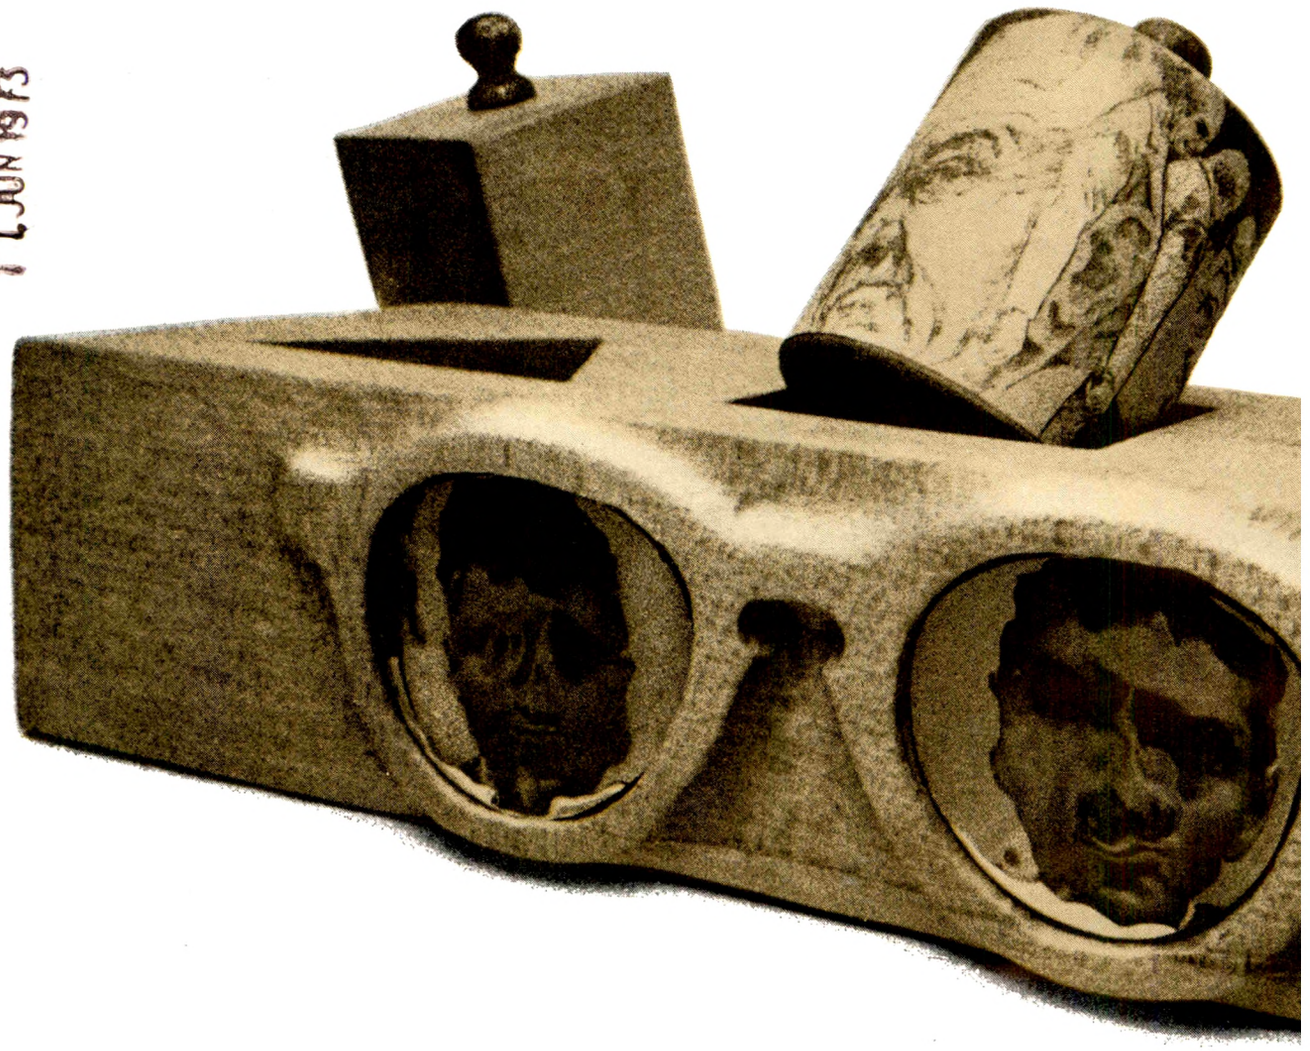
☐ **DRUG ABUSE: Current Concepts and Research** *compiled and edited by* **Wolfram Keup,** *State Univ. of New York Downstate Medical Center, Brooklyn. (70 Contributors)* '72, 496 pp., 20 il., 93 tables, $19.50

☐ **PETS AND HUMAN DEVELOPMENT** *by* **Boris M. Levinson,** *Yeshiva Univ., New York.* '72, 256 pp., 13 tables, $10.50

☐ **EVALUATION AND MANAGEMENT OF THE VIOLENT PATIENT: Guidelines in the Hospital and Institution** *by* **John R. Lion,** *Univ. of Maryland School of Medicine, Baltimore.* '72, 88 pp., $6.00

☐ **THE GENETIC, METABOLIC AND DEVELOPMENTAL ASPECTS OF MENTAL RETARDATION** *edited by* **Robert F. Murray, Jr.** *and* **Pearl Lockhart Rosser,** *both of Howard Univ. College of Medicine, Washington, D. C. Foreword by* **Roland B. Scott.** *(26 Contributors)* '72, 366 pp., 65 il., 15 tables, $16.75

☐ **LAW, LANGUAGE AND COMMUNICATION** *by* **Walter Probert,** *Univ. of Florida, Gainesville. Foreword by* **Harold D. Lasswell.** '72, 408 pp., 10 tables, $13.50



☐ **THE LSD CONTROVERSY: An Overview** *by* **Maurice S. Tarshis,** *Formerly, Alcohol and Drug Section, Mental Health Division, State of Oregon. Foreword by* **Herman A. Dickel.** '72, 96 pp., 1 il., 2 tables, $6.50

☐ **UNDERSTANDING THROUGH COMMUNICATION: Structured Experiments in Self-Exploration** *by* **Lois Timmins,** *Timberlawn Psychiatric Hospital, Dallas. Foreword by* **Howard M. Burkett.** '72, 336 pp., $11.75

Help improve your depressed patients' ability to cope.

1 1 JUN 1973

In Brief:

Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.

Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Close supervision and careful adjustment of dosage are required when this drug is given along with anticholinergic or sympathomimetic drugs. While taking this drug, response to alcoholic beverages may be exaggerated. There is limited clinical experience in the concurrent administration of ECT and antidepressant drugs; thus, one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.

Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

in the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50. 250 and 1000 tablets.

STELAZINE®

brand of

TRIFLUOPERAZINE HCL

Tablets: 1 mg., 2 mg., 5 mg., 10 mg.;
Injection: 2 mg./ml.;
Concentrate: 10 mg./ml.

SK&F offers you six papers by eminent physicians, the latest information available on:

- cost and efficacy relative to other types of therapy
- feasibility and value of drug holidays
- patient response to high-dose therapy
- adverse reactions

To receive this package, clip and mail the coupon.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, a subsidiary of Smith Kline & French Laboratories, Philadelphia, Pennsylvania

1	2	3	4	5
1	2	3	4	5
1	2	3	4	5
1	2	3	4	5

In the course of a four-week trial,** the investigator studied the effects of Valium (diazepam) in 21 psychoneurotic patients, all with marked anxiety and tension and most with associated depressive symptoms. The Valium daily dosage was 15 mg in divided doses, throughout, except for two patients who required a doubling of daily dosage (30 mg). The medication supplemented psychotherapy.

The clinician rated patients' behavior on a modified Brief Psychiatric Rating Scale* before, during, and at the end of treatment. From the individual symptom ratings and the physician's global assessment, it appeared that the concomitant use of Valium and psychotherapy effectively reduced the severity of the anxiety and tension in most patients.

The BPRS itself, it should be observed, was employed as a measure of response to therapy. It is not intended to, nor can it, suggest indications for specific medication.

Of the 21 patients in the group at the outset, four discontinued treatment some time after the second week because of side effects. Eight patients, including the four who stopped medication, reported one or more side effects: 1 constipation; 7 drowsiness/sleepiness; 1 dry mouth; 3 fatigue/exhaustion; 1 gastrointestinal disturbance; 1 insomnia; 2 nervousness/jitteriness/restlessness; 1 nightmares; 1 unpleasant dreams; 1 vertigo.

The patients studied are probably fairly typical of many of your outpatients with marked psychoneuroses. And from the clinical evidence reported over the past nine years, the response to the concomitant use of Valium and psychotherapy seen in this study would also appear to be typical. Valium's beneficial effects can be prompt and pronounced. In recommended dosage, it seldom dulls the senses or interferes with regular activities, although you should caution patients against driving or operating dangerous machinery during therapy. Valium is generally well tolerated: the most common side effects have been drowsiness, ataxia and fatigue.

For individualized treatment, three convenient tablet strengths are available: 2 mg, 5 mg and 10 mg.

*Adapted from the Brief Psychiatric Rating Scale by Overall and Gorham. Nine symptoms deemed inappropriate to this study of anxious psychoneurotic patients were omitted from the original scale.

**Data on file, Medical Department, Hoffmann-La Roche Inc.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

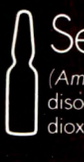
Post-Dryout Mean 3.74
Serentil Mean 2.99
The above is based on the Brief Psychiatric Rating Scale. The difference between the Serentil mean and each of the other scores is statistically significant. Clinical data (based on 17 double-blind studies) on file, Medical Library, Sandoz Pharmaceuticals, East Hanover, N.J.
SER 72-221



EMOTIONAL WITHDRAWAL
CONCEPTUAL DISORGANIZATION / ANXIETY
TENSION / HALLUCINATORY BEHAVIOR
SUSPICIOUSNESS / BLUNTED AFFECT

One or more of these symptoms in a schizophrenic is an indication for

Serentil®

(mesoridazine)

Tablets 50 mg. (as the besylate)

Serentil is also available in injectable form

(Ampuls 1 cc.: 25 mg. mesoridazine [as the besylate]. Inactive ingredients—disodium edetate, U.S.P., 0.5 mg.; sodium chloride, U.S.P., 7.2 mg.; carbon dioxide gas [bone dry], q.s.; water for injection, U.S.P., q.s. to 1 cc.)

SANDOZ

EMOTIONAL WITHDRAWAL
CONCEPTUAL DISORGANIZATION / ANXIETY
TENSION / HALLUCINATORY BEHAVIOR
SUSPICIOUSNESS / BLUNTED AFFECT

One or more of these symptoms in a schizophrenic is an indication for

Contraindications: Severe central nervous system depression, comatose states, hypersensitivity.

Warnings: Increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence, it should be given only when the anticipated benefits to be derived from treatment exceed the possible risks to mother and fetus. Use in children under 12 is not recommended. Phenothiazines are capable of potentiating central nervous system depressants as well as atropine and phosphorus insecticides.

Precautions: Ocular changes (seen with other phenothiazines) have not been seen with Serentil (mesoridazine). Because of possible hypotensive reactions, caution in parenteral use is required. Reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. Blood dyscrasia (seen with other phenothiazines) has occurred in a single case of transient granulocytopenia.

Adverse Reactions: Serentil (mesoridazine) has demonstrated a remarkably low incidence of adverse reactions when compared with other phenothiazine compounds. *Central Nervous System:* Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Endocrine System:* Inhibition of ejaculation and lactation have been noted rarely. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension, tachycardia, EKG changes.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. There is no evidence that these changes are precursors of any significant disturbance of cardiac rhythm. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia, behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

Dosage and Administration: ORAL: Should be adjusted to needs of the individual. Lowest effective dosage should always be used. When maximum response is achieved, dosage may be reduced gradually to maintenance level. *Schizophrenia:* For most patients, regardless of severity, starting dose of 50 mg. t.i.d. recommended. Usual optimum total daily dose range 100-400 mg. *Behavioral Problems in Mental Deficiency and Chronic Brain Syndrome:* For most patients starting dose of 25 mg. t.i.d. recommended. Usual optimum total daily dose range 75-300 mg. *Alcoholism:* For most patients usual starting dose is 25 mg. b.i.d. Usual optimum total daily dose range 50-200 mg. *Psychoneurotic Manifestations:* For most patients usual starting dose is 10 mg. t.i.d. Usual optimum total daily dose range 30-150 mg. INJECTABLE FORM: For situations in which an intramuscular form of medication is indicated. For most patients a starting dose of 25 mg. is recommended, to be repeated in 30-60 minutes if necessary. Usual optimum total daily dose range 25-200 mg.

Before prescribing, consult package circular.

UNDERSTANDING MENTAL HEALTH . . .

A New Book! **Butler-Lewis**

AGING AND MENTAL HEALTH

Positive Psychosocial Approaches

Gain a down-to-earth understanding of how you can help the elderly reach their full potential with this unique new book that gives the *complete* picture of the aged in America — including economic and everyday aspects. Aging is stressed as a normal process, with emphasis given to mental health factors and intervention in both institutional and non-institutional settings.

By ROBERT N. BUTLER, M.D.; and MYRNA I. LEWIS, ACSW. April, 1973. Approx. 320 pages, 7" x 10", 25 illustrations. About $5.95.

A New Book! **Fann-Goshen**

THE LANGUAGE OF MENTAL HEALTH

End confusion over your field's terminology with this new book that clarifies and explains over 2,555 terms. Terminology is included on abnormal psychology, behavorial science, and clinical, administrative and legal areas. Informative biographies of individuals who have made significant contributions to the field of mental health are summarized.

By WILLIAM E. FANN, M.D.; and CHARLES E. GOSHEN, M.D. March, 1973. 132 pages & FM I-X, 7" x 10". $5.95.

New 5th Edition! **Ulett**

A SYNOPSIS OF CONTEMPORARY PSYCHIATRY

This highly readable presentation of clinical psychiatry reflects today's trend to a psychodynamic approach to mental illness. In factual outline form, it gives basic information on mental illness and clarifies new findings on the use of depth electrodes in taking EEG's and on the use of EEG's in diagnosing epilepsy, drug and toxic encephalopathy.

By GEORGE A. ULETT, A.B., M.S., M.D., Ph.D. July, 1972. 5th edition, 367 pages plus FM I-XIV, 4⅞" x 7⅝". $10.90.

HEL S KEE THE E L IN REALITY

Effective Management of Psychotic Symptoms

- Calms hyperactive behavior
- Controls hostility
- Decreases delusions, auditory and visual hallucinations
- Allays underlying fear, anxiety and tension
- Lessens unusual thought content, paranoid ideation
- Reduces emotional withdrawal

Before prescribing, see complete prescribing information including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders.

Probably effective: For control of the manifestations of manic-depressive illness (manic phase). For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

Wednesday's child is full of woe

It need not be this way for the MBD child.

He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

(methylphenidate hydrochloride)

TABLETS

INDICATION
Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)
Special Diagnostic Considerations
Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.
The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.
Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.
Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION
Children with Minimal Brain Dysfunction (6 years and over)
Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.
If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.
Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.
Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.

is indicated

C I B A

The challenge: versatility

The stereotype image of "psychiatrist and couch" is an anachronism because today's psychiatrist is called on to diagnose and treat depression in a variety of clinical settings. And when an antidepressant medication is chosen, it must be as flexible and as adaptable as the physician prescribing it.

The psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL® (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

The general hospital today usually provides a psychiatric unit where depressed patients are treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic, where follow-up treatment may be necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital, severely depressed patients present challenges for psychiatrist and staff alike. Here, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

The community mental health center, a remarkable innovation in the field of modern psychiatry, offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

helps open many doors

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

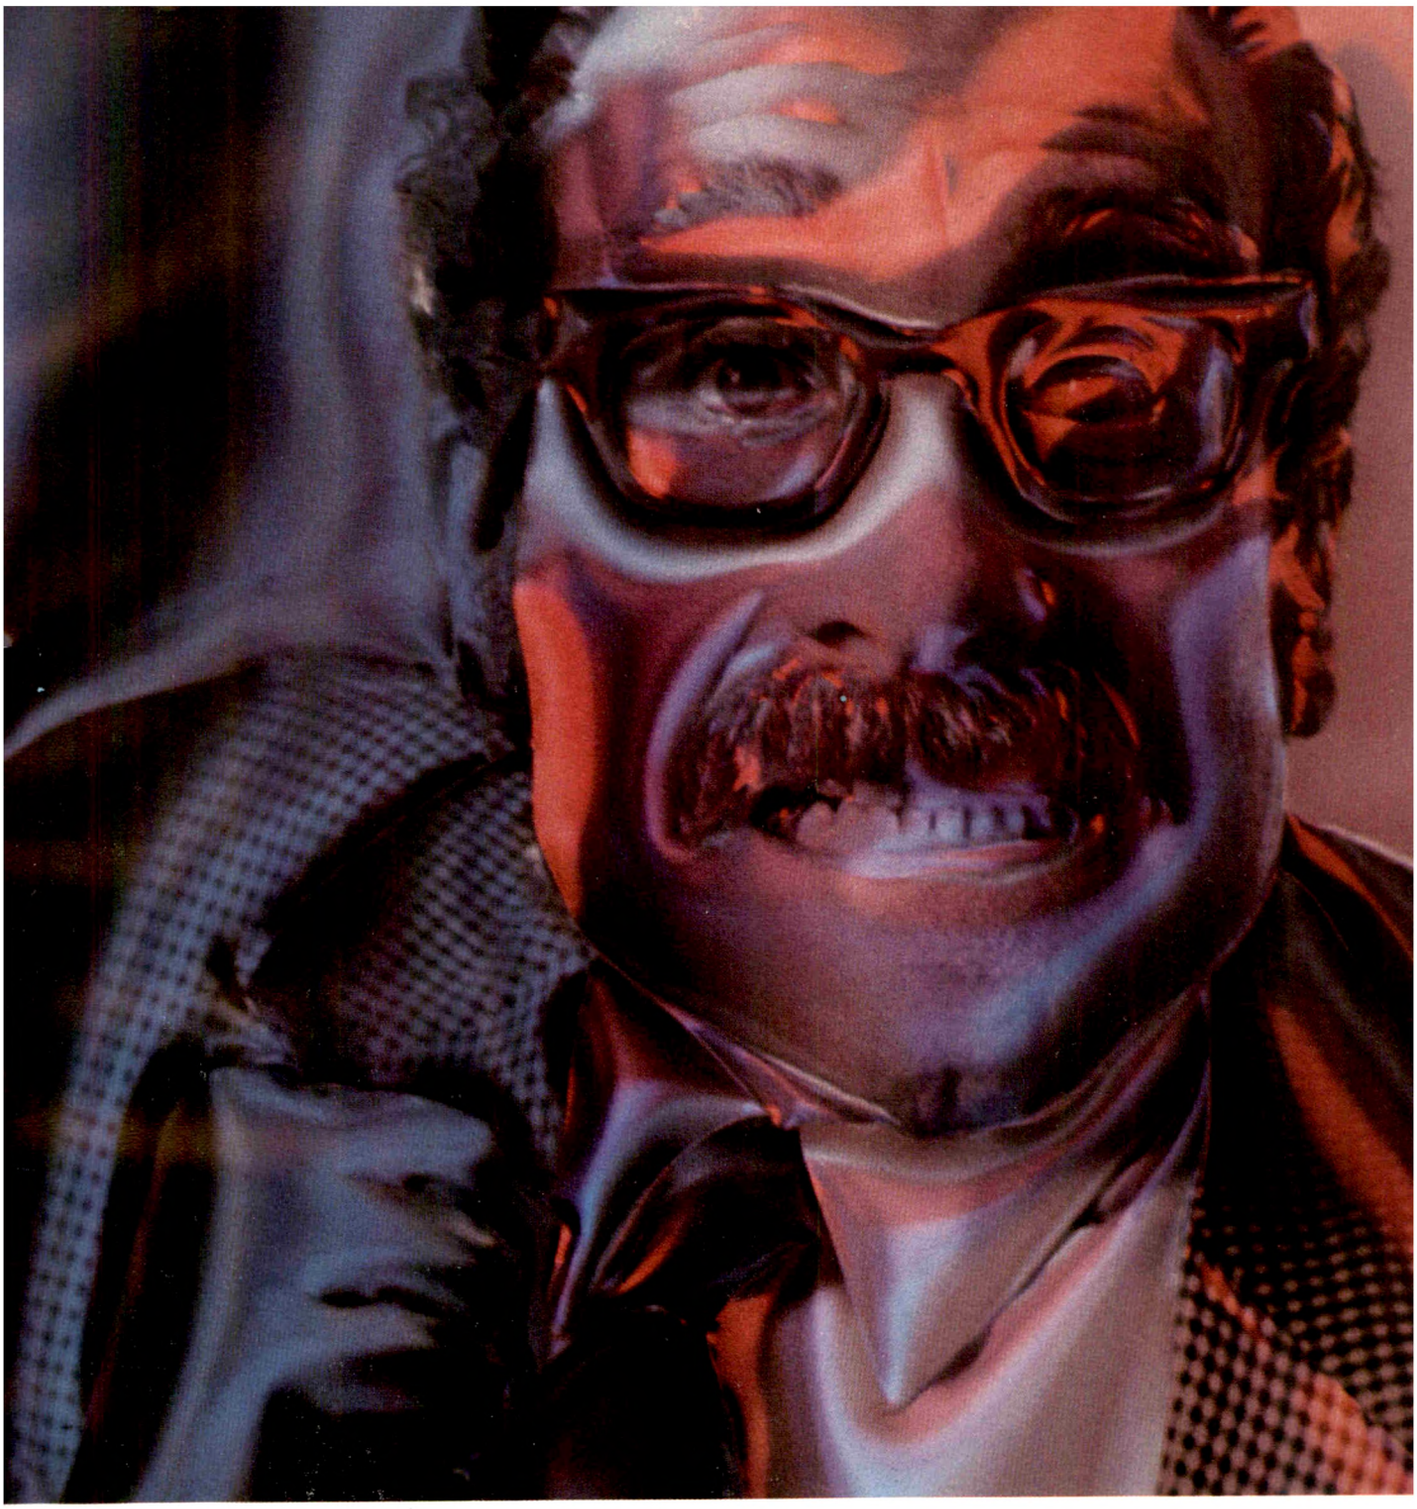
a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction or for patients under 12 years of age.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.



Overdosage: The intravenous administration of 1–3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

(AMITRIPTYLINE HCl | MSD)
helps open many doors

Agitated and hyperactive?...Or cooperative?

While psychotic symptoms remain acute, the barrier between you and the agitated, hyperactive patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

cooperation often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

Haldol®
(HALOPERIDOL)

a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

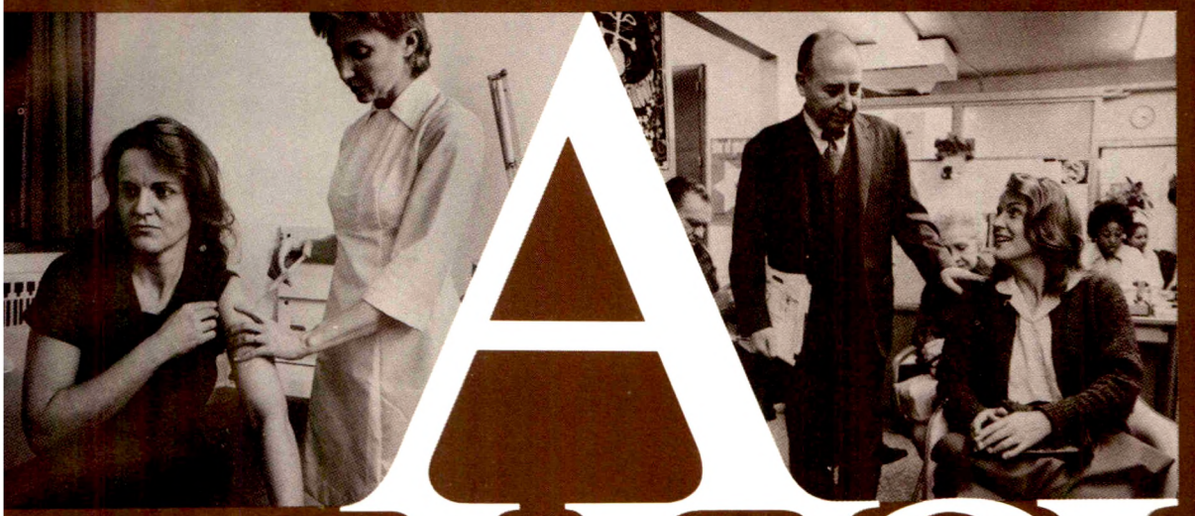
Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General—Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.



Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

For schizophrenic patients...

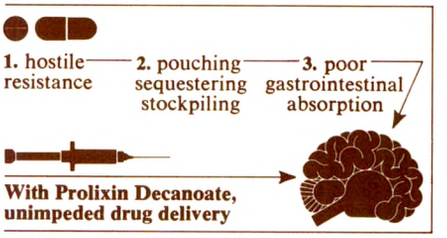
A way out:

...that helps keep them out

Controlled Drug Delivery

with new

PROLIXIN® DECANOATE



(FLUPHENAZINE DECANOATE INJECTION)

Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer with an average duration of effect of about 2 weeks

Controlled drug delivery – a revolution in patient management

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) HELPS ASSURE EFFECTIVE, UNHINDERED MEDICATION

Controlled drug delivery is *physician*-controlled delivery, an effective prophylactic maneuver against disruption of therapy–one of the most common causes of psychotic relapse. Is the patient taking his medication? You know because you administer it or direct others to. Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.

In most patients, symptomatology is controlled by Prolixin Decanoate for periods of two weeks with a single injection. Sequestered medication and similar problems associated with oral therapy are not encountered. Nor does the patient risk drug loss through severe diarrhea or poor gastrointestinal absorption. Prolixin Decanoate keeps the patient medicated...helps make him more amenable to the entire treatment program and improves his chances for rehabilitation and discharge.

The outpatient is vulnerable to the dictates of his own poor judgment. Deluded by a sense of well-being, he may question the need for medication. Family and friends often give him misleading advice. Oral therapy in such a patient encourages missed doses. Medication with Prolixin Decanoate (Fluphenazine Decanoate Injection) helps assure drug delivery when required and in the dosage prescribed. It helps keep the outpatient out.

FOUR REASONS FOR READMISSION...

For brief summary, see last page of this presentation.

ROLIXIN® DECANOATE
luphenazine Decanoate Injection)
SURES ECONOMIC DRUG
ELIVERY...LESS FREQUENT
OSING THAN WITH ORAL
IERAPY

Controlled drug delivery brings cost therapy down with less hospitalization, less nursing time, less frequent sing. Low annual dosage means less st for the hospital, for the patient's nily, and for the community. It ans a minimum of drug holidays to oid long-term complications, with ir confusing schedules for patient d family.

ntrolled drug delivery—
evolution in the treatment of the hizophrenic patient

ROLIXIN® DECANOATE
luphenazine Decanoate Injection)
ELPS ENHANCE LIKELIHOOD
F DISCHARGE

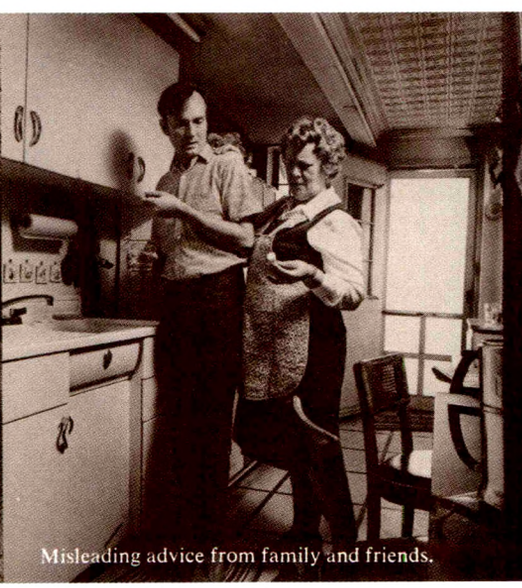
Optimally, the mental hospital ould be a rehabilitating bridge beeen life before and life after custoal care. Prolixin Decanoate often ortens that bridge because getting the patient out is frequently a matter of eping him medicated. And 1 injecon of Prolixin Decanoate means apoximately 2 weeks of symptom ntrol. The importance of control by e physician with this injectable can seen in the fact that about 1 out of ery 5 inpatients does not take his tabs even when they are administered by nursing staff. With controlled drug delivery, lost or hidden doses are not a problem.

In one study,[1] 24 chronic long-term hospital patients were treated with Prolixin Decanoate in dosages of 12.5 mg. to 75 mg. given every 7 days to 3 weeks. Most of the patients received 25 to 50 mg. per injection. Of these, 13 were discharged after 6 months of treatment, 4 were considered dischargeable, and 7 did not improve. In 12 of the 24 patients who previously had been on different psychotropic drugs for periods of 4 to 96 weeks, improvement with Prolixin Decanoate (Fluphenazine Decanoate Injection) was observed in affect, volition, and higher mental functions. Dischargeability in these patients "may also have been enhanced because the staff, the patient, and the family were assured of an adequate and regular medication intake."[1]

Controlled drug delivery—
a revolution in the care of the outpatient

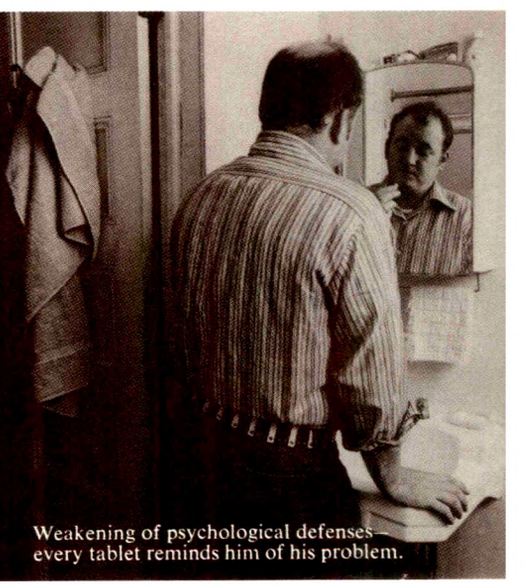
PROLIXIN® DECANOATE
(Fluphenazine Decanoate Injection)
PROMOTES CONTINUITY OF MEDICATION WITH DIMINISHED LIKELIHOOD OF RELAPSE COMPARED WITH ORAL THERAPY

Success in rehabilitative areas like employment and social acceptance depends in large measure on adequate and continuing phenothiazine intake; success in family adjustment no less so. Short-acting medication is not the best path to such success. According to one report,[2] "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication." And McClellan and Cowan[3] state that a substantial number of patients taking antipsychotic drugs do so in amounts significantly less than those prescribed. Even once-daily administration does not solve the problem of poor home supervision or the patient's lack of insight into his condition.



Controlled drug delivery with Prolixin Decanoate (Fluphenazine Decanoate Injection) is an efficient route to continuity of medication, and therefore to long-term remission. For one thing there is less strain on the patient's often tenuous adjustment to family living. Since family members are not responsible for supervising the patient's medical needs, they tend to be more accepting, and better feeling is promoted merely because the controlled delivery regimen demonstrates that improvement is possible. Controlled drug delivery also strengthens the patient's psychological defenses. He is not reminded of his psychiatric illness by multiple daily doses.

The same unique advantages of controlled drug delivery with Prolixin Decanoate that promote the discharge-

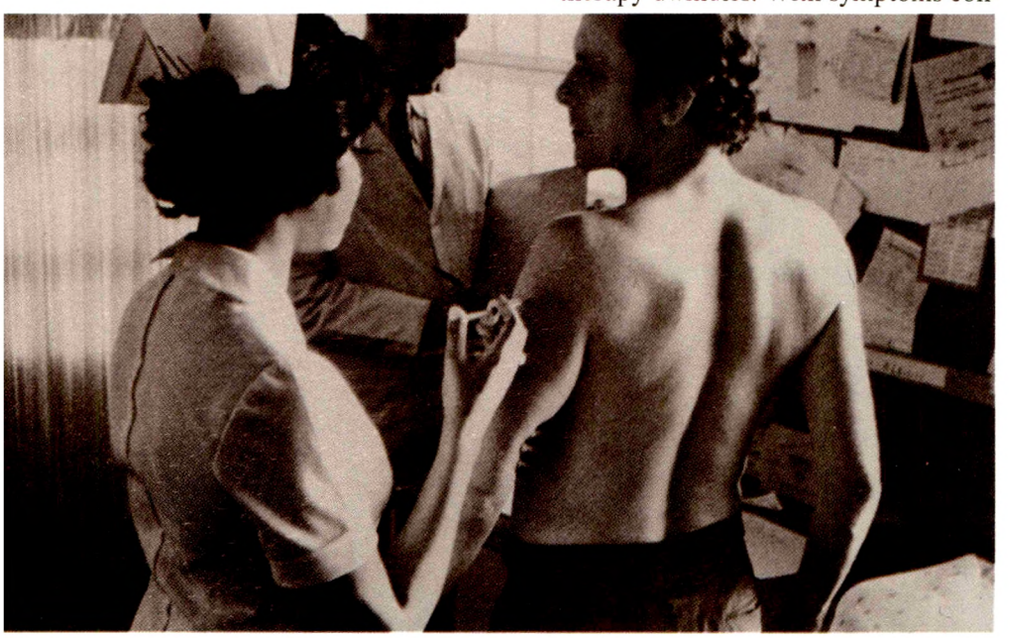


(Continued on following page)

ockpiling.

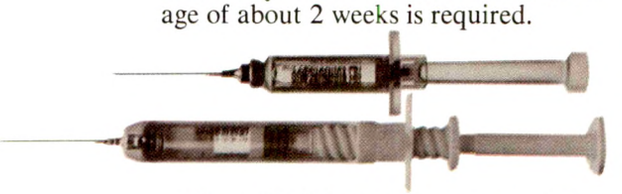
Misleading advice from family and friends.

Weakening of psychological defenses—every tablet reminds him of his problem.



OOD REASONS FOR CONTROLLED DRUG DELIVERY

(Continued from preceding page)
ability of the inpatient and help maintain him in the community are true for the patient who has never been hospitalized. It is just these advantages that will help the physician or psychiatrist keep him in the community without the need for custodial care.



Controlled drug delivery — a revolution in efficiency of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) SAVES TIME, REDUCES COST IN THE HOSPITAL, CLINIC, OFFICE

Controlled drug delivery saves time, reduces costs in the hospital. With Prolixin Decanoate there can be no palming, pouching, regurgitating. With Prolixin Decanoate resistance to therapy dwindles. With symptoms con-

trolled, the patient is more manageable, more comfortable, more amenable to the total hospital treatment program. With Prolixin Decanoate only 1 dose visit every 1 to 3 weeks with an average of about 2 weeks is required.

Controlled drug delivery saves time, reduces costs in the clinic and office.

With Prolixin Decanoate less frequ
dosing. With Prolixin Decanoate (F
phenazine Decanoate Injection) m
patients report for their injections o
once in every 2-week period.

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY
Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anti-cholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of anti-parkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage. A persistent and sometimes irreversible pseudo-parkinsonian syndrome may develop with chronic administration of phenothiazine compounds. Rhythmic, stereotyped dyskinetic involuntary movements, particularly of the face, mouth, tongue and jaw occur, and may be accompanied by choreiform movements of the limbs. The symptoms persist after drug withdrawal. Anti-parkinsonian agents are seldom of benefit. The risk appears to be greatest in elderly females with organic brain damage receiving large and prolonged doses. Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

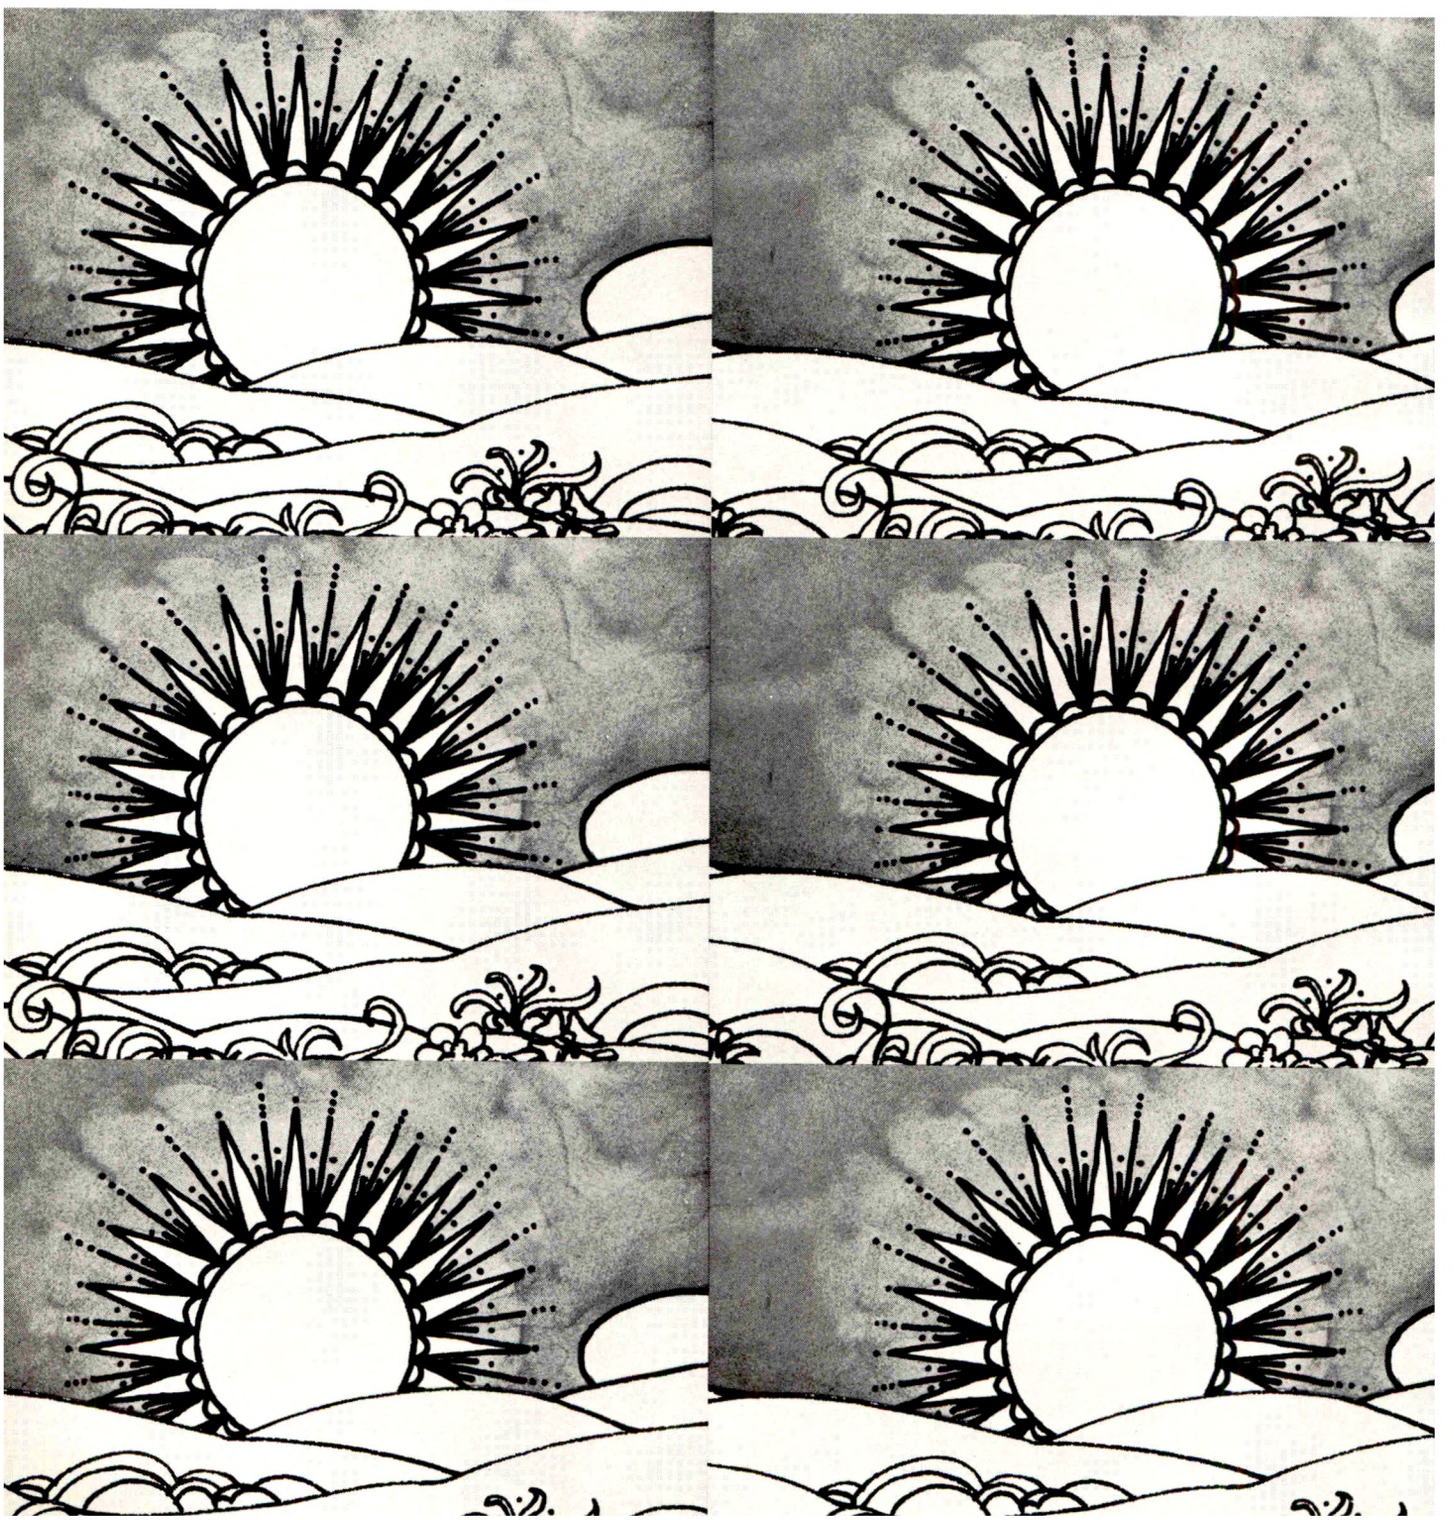
Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.



Supply: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

SQUIBB HOSPITAL DIVISION

© 1973 E. R. Squibb & Sons, Inc. H783-004
Princeton, N.J. 08540

The new-day constant for drug-induced parkinsonism:

ARTANE®
TRIHEXYPHENIDYL HCl

Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

Tablets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

Tablets and Elixir Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

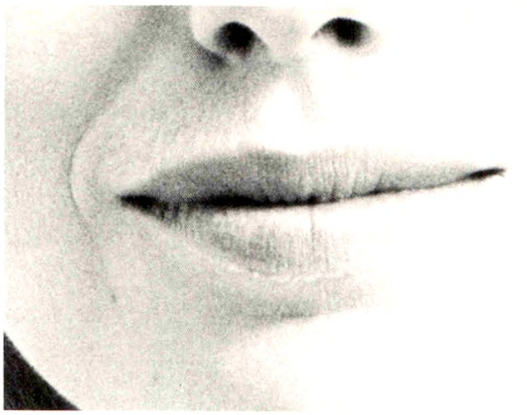
***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

WARNING:
Patients to be treated should have a gonioscope evaluation and close monitoring of intraocular pressures at regular periodic intervals.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.



*This drug in sustained release form has been evaluated as probably effective. See Brief Summary.

Lederle LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York 10965

716-3

A25

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Not recommended for use in children. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug, such as perphenazine, concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, close supervision and careful adjustment of dosages are required. In healthy test subjects, maximum therapeutic doses significantly potentiated the peripheral circulatory effects of intravenous norepinephrine and epinephrine (manifested by undue increase in systolic and diastolic blood pressure and decrease in pulse rate). May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent administration with electroshock therapy may increase the hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue the drug several days before elective surgery, if possible.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, arrhythmias.

CNS and Neuromuscular: confusional states (especially in the elderly); disorientation; delusions; hallucinations; anxiety; agitation; restlessness; insomnia; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremor; seizures.

Anticholinergic: dry mouth and, rarely, associated sublingual adenitis; blurred vision; disturbance of accommodation; mydriasis; constipation; urinary retention; dilatation of the urinary tract.

Other: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), nausea, vomiting, epigastric distress, anorexia, peculiar taste, stomatitis, parotid swelling, impotence, jaundice (simulating obstructive), drowsiness, dizziness, weakness, fatigue, headache, perspiration, weight gain or loss, urinary frequency.

Withdrawal Symptoms: In an occasional patient, abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

The following adverse reactions have been reported less frequently with the class of antidepressant agent to which protriptyline HCl belongs: myocardial infarction, heart block, stroke, panic, nightmares, alteration in EEG patterns, hypomania, exacerbation of psychosis, extrapyramidal symptoms, tinnitus, paralytic ileus, delayed micturition, drug fever, bone-marrow depression, agranulocytosis, eosinophilia, purpura, thrombocytopenia, diarrhea, abdominal cramps, black tongue, testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, altered liver function, flushing, nocturia, alopecia.

Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

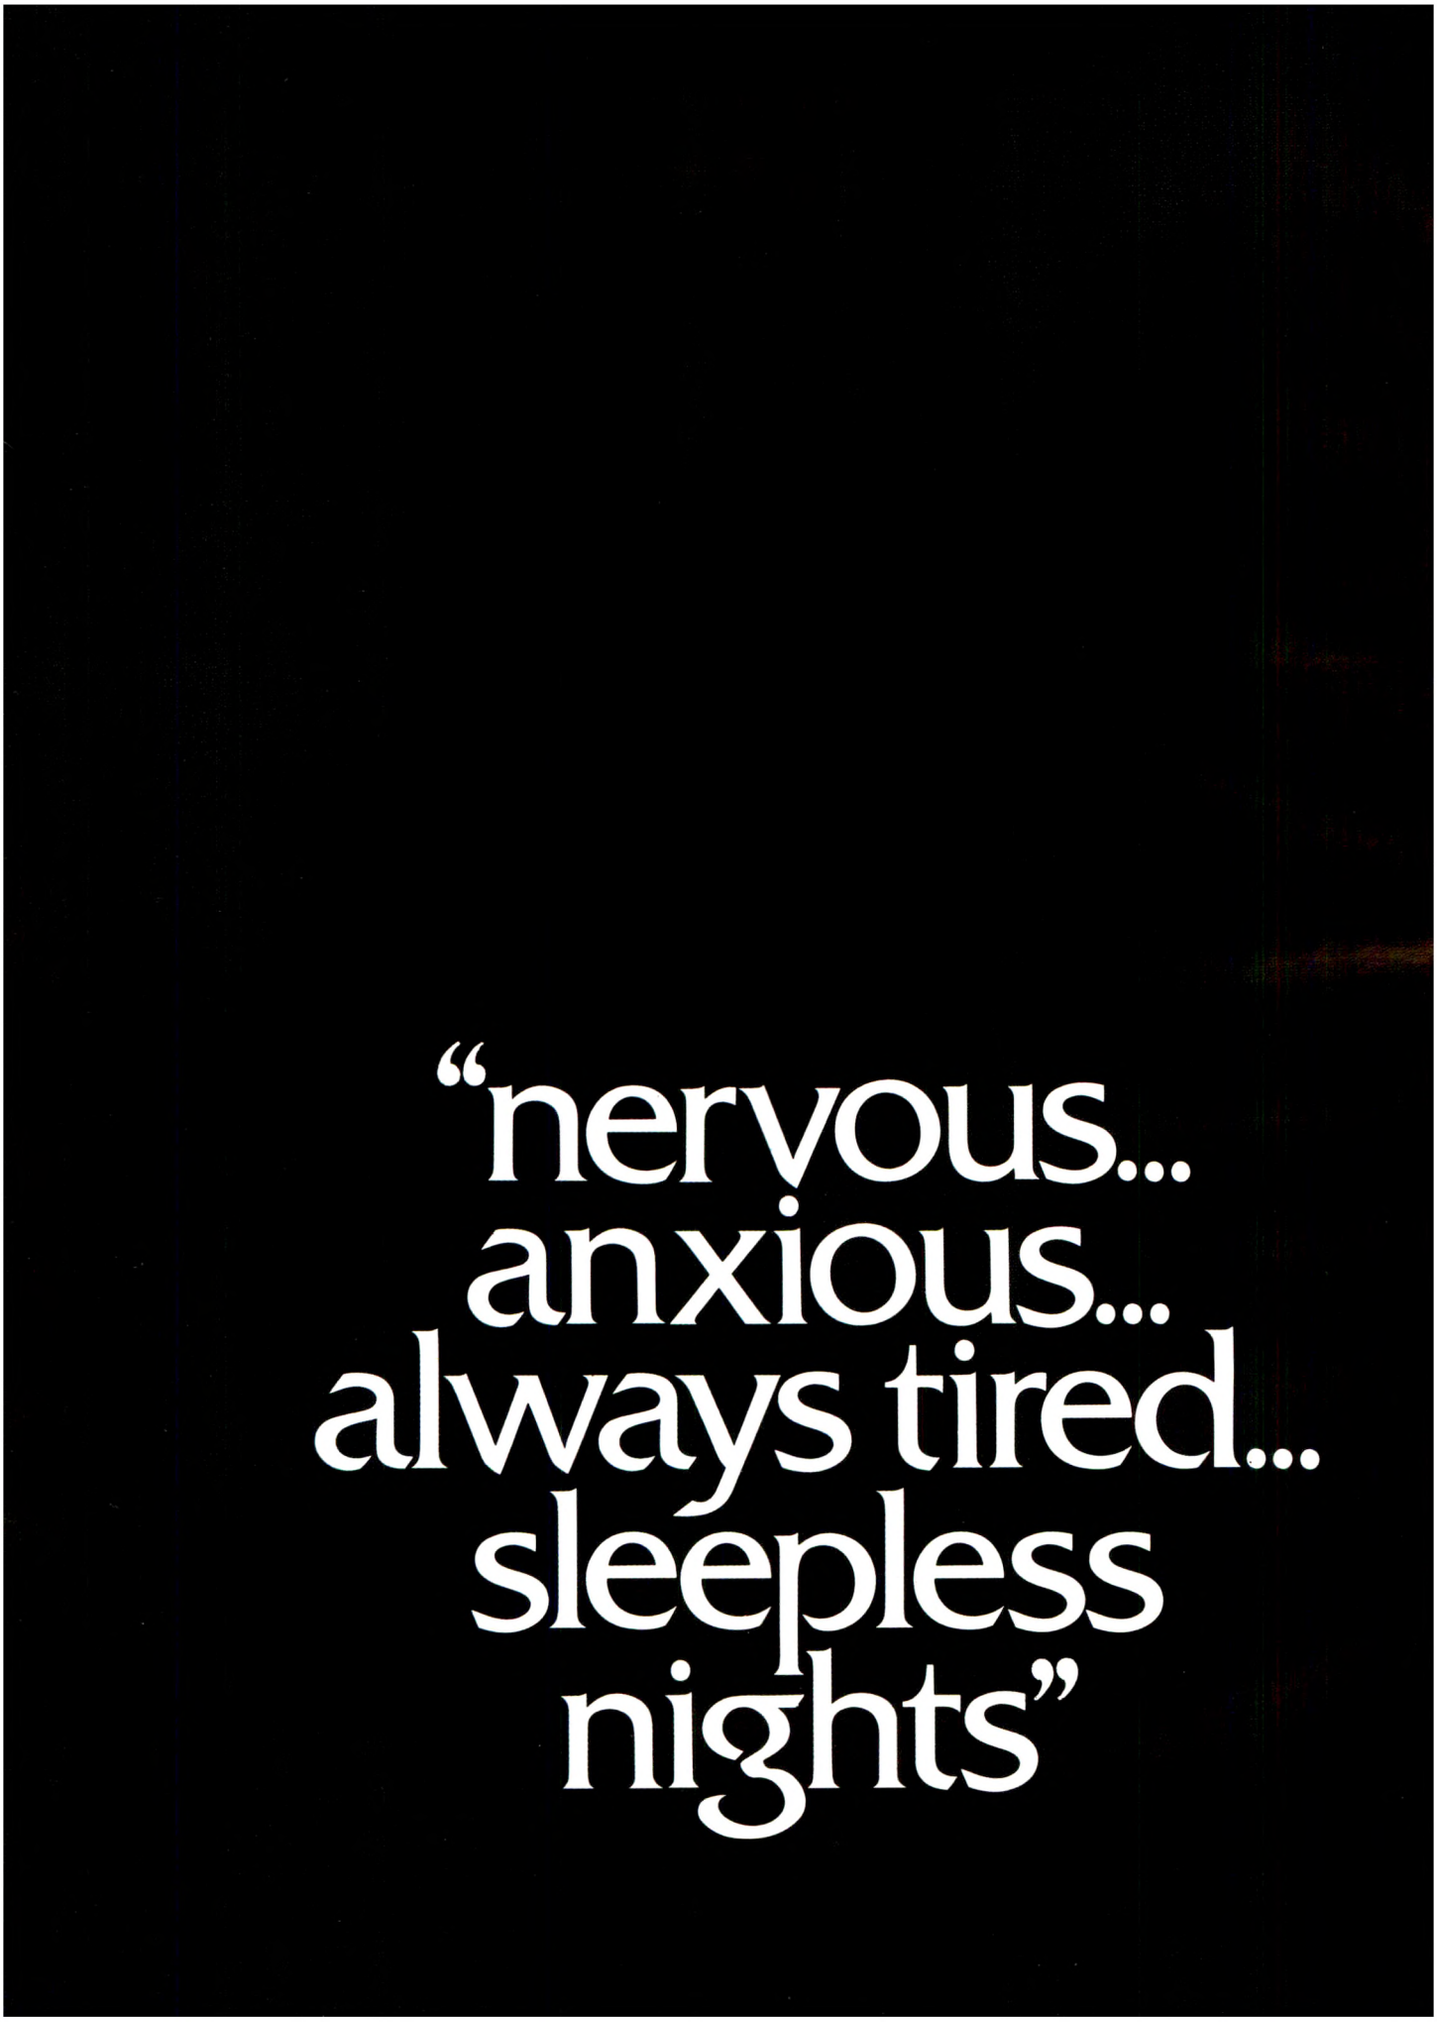
For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

addendum

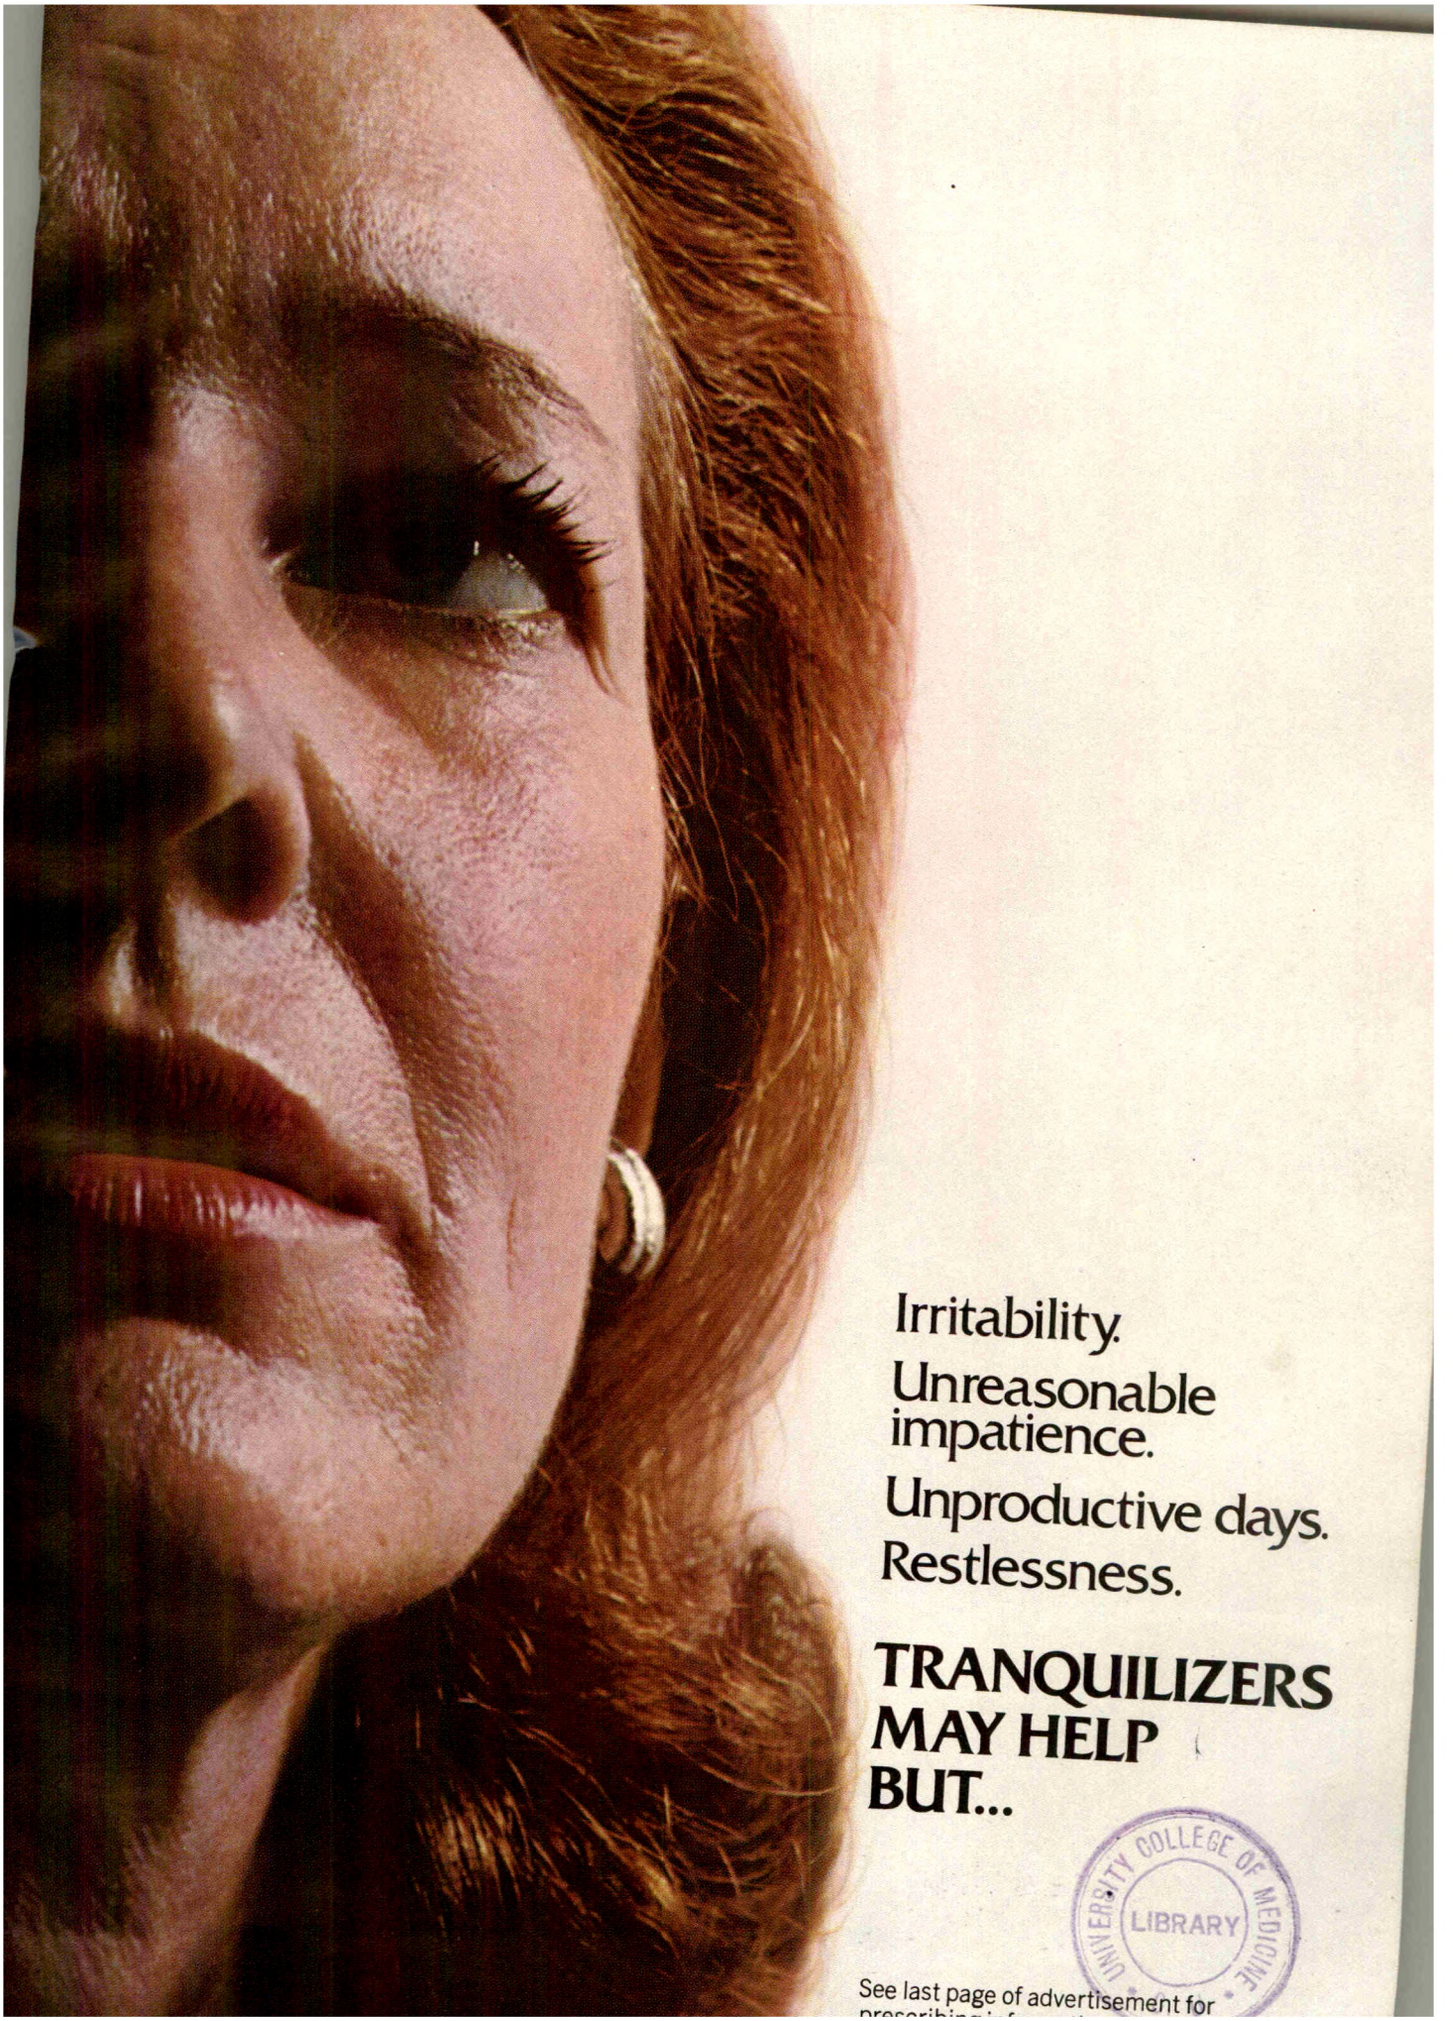
MSD
MERCK
SHARP
DOHME

5 mg (orange)

10 mg (yellow)



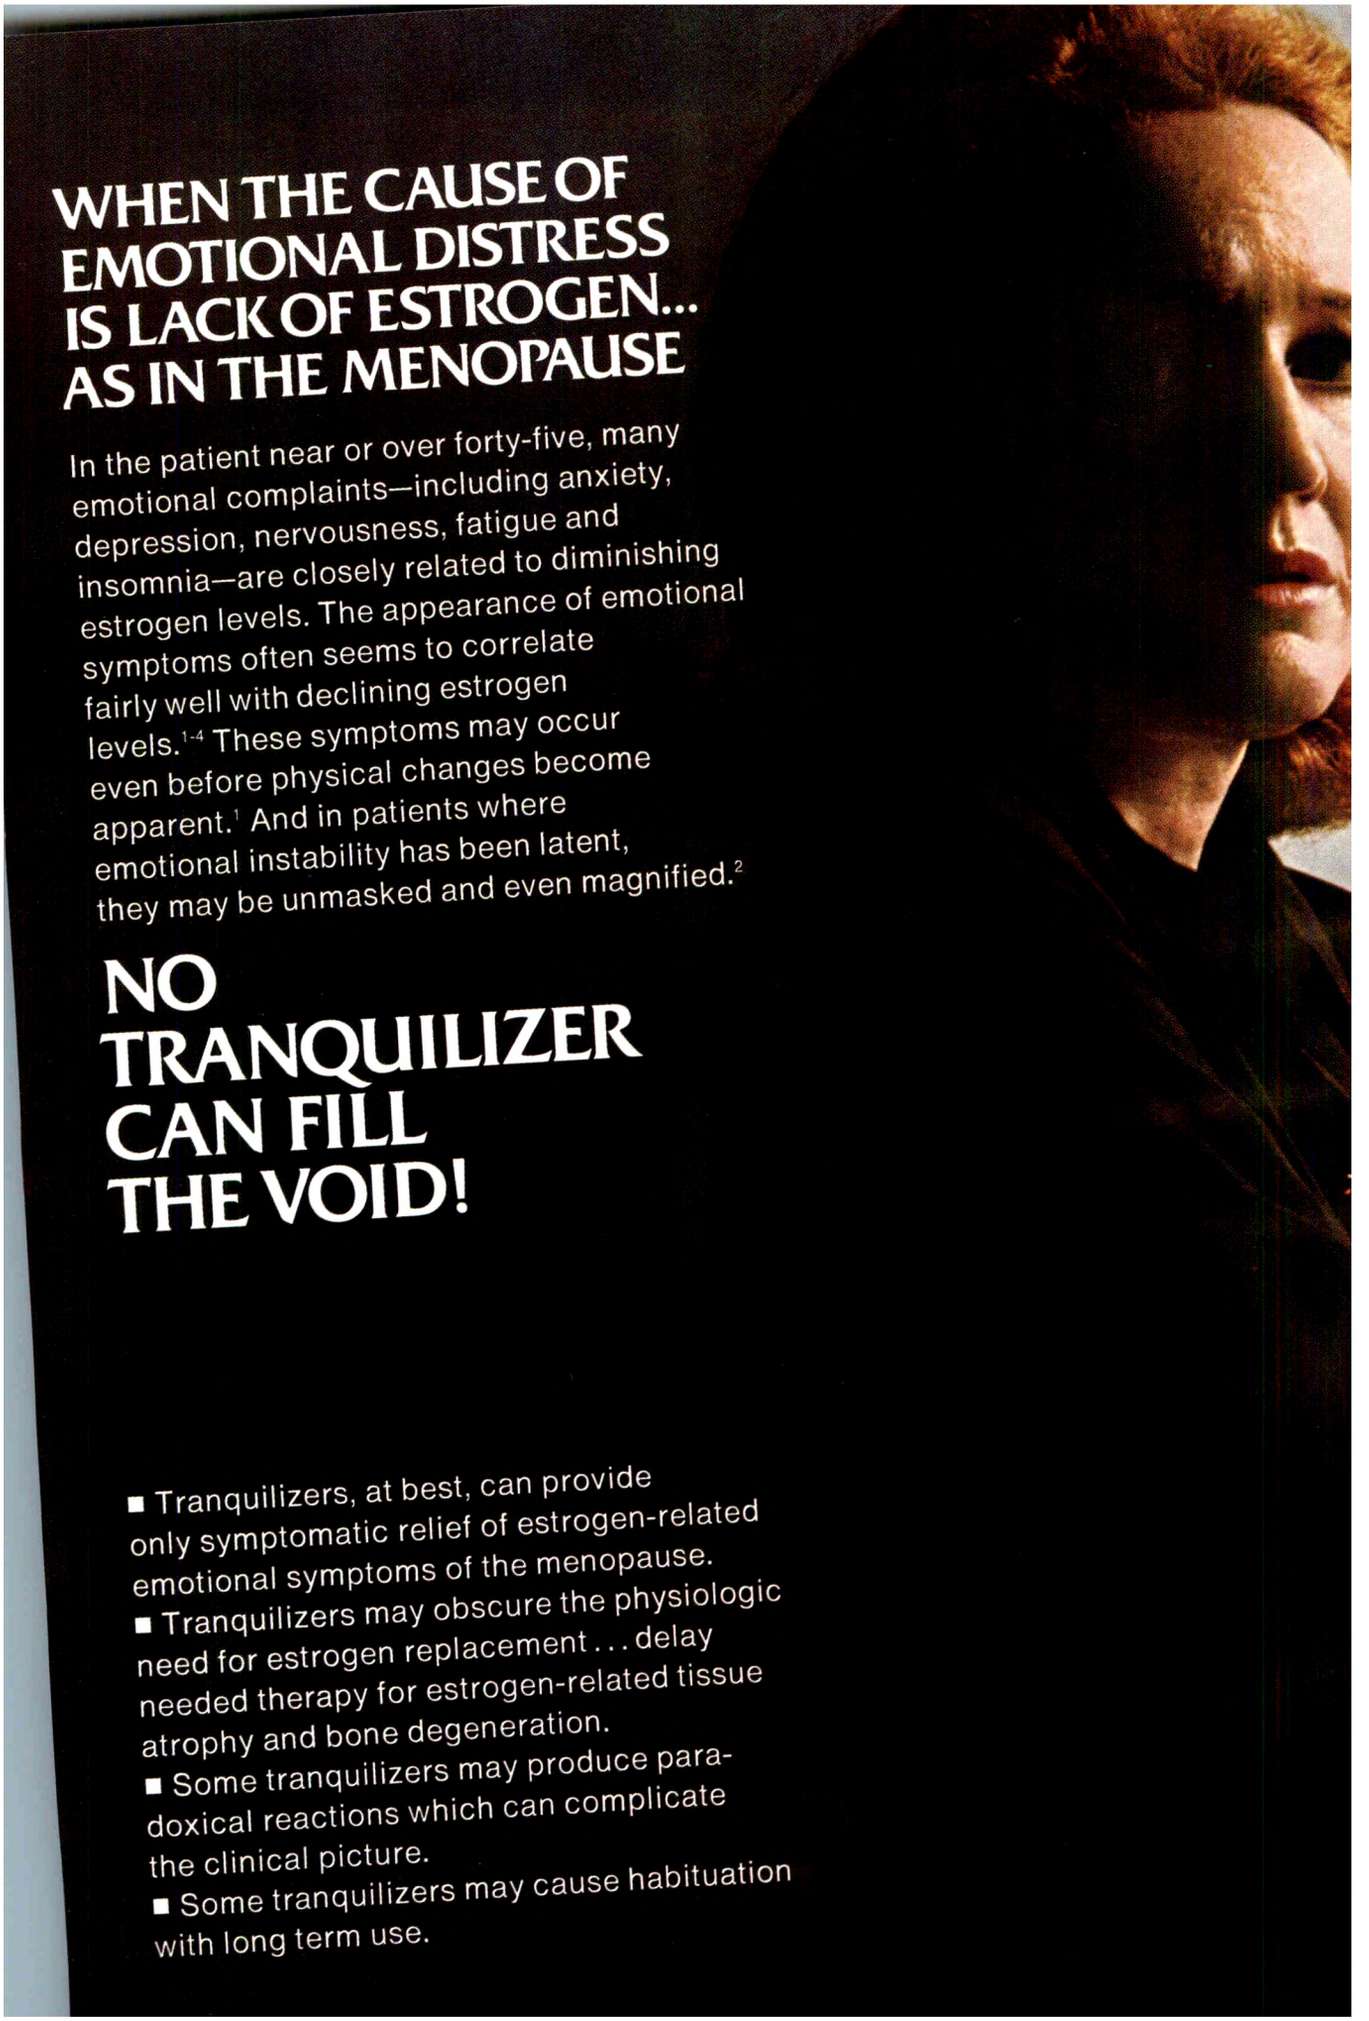
The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.



In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.



(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

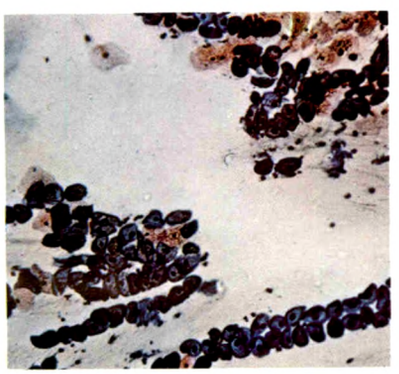
WHEN THE CAUSE OF EMOTIONAL DISTRESS IS LACK OF ESTROGEN... AS IN THE MENOPAUSE

In the patient near or over forty-five, many emotional complaints—including anxiety, depression, nervousness, fatigue and insomnia—are closely related to diminishing estrogen levels. The appearance of emotional symptoms often seems to correlate fairly well with declining estrogen levels.[1-4] These symptoms may occur even before physical changes become apparent.[1] And in patients where emotional instability has been latent, they may be unmasked and even magnified.[2]

NO TRANQUILIZER CAN FILL THE VOID!

- Tranquilizers, at best, can provide only symptomatic relief of estrogen-related emotional symptoms of the menopause.
- Tranquilizers may obscure the physiologic need for estrogen replacement . . . delay needed therapy for estrogen-related tissue atrophy and bone degeneration.
- Some tranquilizers may produce paradoxical reactions which can complicate the clinical picture.
- Some tranquilizers may cause habituation with long term use.



By providing sound specific natural estrogen replacement, PREMARIN does what tranquilizers, sedatives, and antidepressants can't possibly do —relieves estrogen-related emotional symptoms of the menopause by treating the underlying deficiency.

At the same time, PREMARIN helps control physiologic symptoms of estrogen depletion, such as hot flushes, sweats, genital tissue atrophy, and, in selected cases, helps retard postmenopausal osteoporotic bone degeneration.†

Estrogen-related anxiety and depression usually respond to estrogen replacement therapy in a relatively short time.[3,5] Other "psychogenic" symptoms such as headaches, crying spells, insomnia, feelings of weakness and fatigue may also be relieved.[1,3,4,6] And in a large majority of patients, PREMARIN imparts a renewed sense of well-being.[7] PREMARIN. It gives patients back something they've lost. No tranquilizer can do that.

Whether your patient is a woman of forty-five suffering from estrogen-related emotional distress . . . or a grandmother of fifty-five with atrophic vaginitis . . . or a septuagenarian with osteoporosis and chronic back pain, she may often benefit from continued replacement therapy with PREMARIN.

PREMARIN is a natural estrogen. It contains natural estrogens exclusively—no synthetics. And PREMARIN provides the complete estrogen complex. Of all leading oral estrogens, it is the only one whose composition meets every specification for conjugated estrogens listed in the latest United States Pharmacopeia (Edition XVIII). PREMARIN. Thirty years of proven efficacy and patient acceptance. Virtually free from side effects. It's the most widely prescribed agent of its kind.

Patient, age 47, before therapy.* Vaginal cytogram shows virtual absence of superficial cells, indicating estrogen depletion: Superficial cells—5%/Intermediate cells—25%/Parabasal cells—70%.

Patient after PREMARIN therapy.* Vaginal cytogram shows reappearance of superficial cells, indicating improved estrogen status: Superficial cells—85%/Intermediate cells—15%/Parabasal cells—0%.

*Case report on file, Medical Department, Ayerst Laboratories, New York, N.Y.

RELIEVES HER SYMPTOMS AND CONTROLS THEIR CAUSE

†This drug has been evaluated as "probably" effective for postmenopausal osteoporosis.

Ayerst®

See last page of advertisement for Prescribing Information.

(Complete text of package circular.)

PREMARIN® (Conjugated Estrogens Tablets, U.S.P.)

Description: PREMARIN (Conjugated Estrogens, U.S.P.) is a mixture of estrogens, obtained exclusively from natural sources, occurring as the sodium salts of water-soluble estrogen sulfates blended to represent the average composition of material derived from pregnant mares' urine. It contains estrone, equilin, and 17*a*-dihydroequilin, together with smaller amounts of 17*a*-estradiol, equilenin, and 17*a*-dihydroequilenin as salts of their sulfate esters.

Actions: Estrogens are responsible for development and maintenance of the female reproductive system and secondary sex characteristics. They cause the growth and development of the vagina, uterus, and fallopian tubes, and enlargement of the breasts. Indirectly, they contribute to the shaping of the skeleton, maintenance of tone and elasticity of urogenital structures, changes in the epiphyses of the long bones that allow for pubertal growth spurt and termination, growth of axillary and pubic hair, and pigmentation of the nipples and genitals. Estrogens are also involved in psychologic and emotional aspects of feminine behavior. As estrogen levels increase during the menstrual cycle, there is a sense of vigor and well-being, and in the menopausal period estrogens aid in relieving nervous symptoms (e.g. anxiety, depression and irritability) due to estrogen deficiency. Decline of estrogenic activity at the end of the menstrual cycle can bring on menstruation, although the cessation of progesterone secretion is the most important factor in the mature ovulatory cycle. However, in the pre- or non-ovulatory cycle, estrogen is the primary determinant in the onset of menstruation. Estrogens do not induce ovulation.

Estrogens affect calcium and phosphorus metabolism, and are involved in maintenance of normal bone structure. In prolonged estrogen deficiency states, administration of estrogen acts to prevent associated bone degenerative changes.

Estrogens appear to be responsible for the relatively greater amount of alpha-lipoprotein and correspondingly lower amount of beta-lipoprotein found in premenopausal women as compared with men.

Estrogens affect the release of pituitary gonadotropins and may also deplete the gonadotropic content of the pituitary.

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications for use as follows:

Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus; female hypogonadism; amenorrhea; and primary ovarian failure.

For abnormal uterine bleeding due to hormonal imbalance in the absence of organic pathology such as submucosal fibroids or uterine cancer.

For prevention of postpartum breast engorgement; also for inoperable progressing prostatic cancer (for palliation only when castration is not feasible or when castration failures or delayed escape following a response to castration have not occurred); breast cancer (for palliation only in women with progressing inoperable or roentgen resistant disease who are more than 5 years postmenopausal).

"Probably" effective: For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short-acting estrogens are contraindicated in patients with (1) markedly impaired liver function; (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.

Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.

The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.

Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.

Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.

A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.

Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.

Precautions: As with all short-acting estrogens, the following precautions should be observed:

A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.

To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period—withdrawal bleeding may occur during rest period).

Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.

Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.

If unexplained or excessive vaginal bleeding should occur, re-examination should be made for organic pathology.

Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.

The pathologist should be advised of estrogen therapy when relevant specimens are submitted.

Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.

Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.

The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.

Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.

Adverse Reactions: The following adverse reactions have been reported associated with short-acting estrogen administration:

- nausea, vomiting, anorexia
- gastrointestinal symptoms such as abdominal cramps and bloating
- breakthrough bleeding, spotting, unusually heavy withdrawal bleeding (See DOSAGE AND ADMINISTRATION)
- breast tenderness and enlargement
- reactivation of endometriosis
- possible diminution of lactation when given immediately postpartum
- loss of libido and gynecomastia in males
- edema
- aggravation of migraine headaches
- change in body weight (increase, decrease)
- headache
- allergic rash
- hepatic cutaneous porphyria becoming manifest

Dosage and Administration: PREMARIN (Conjugated Estrogens Tablets, U.S.P.) should be administered cyclically (3 weeks of daily estrogen and 1 week off) for all indications except selected cases of carcinoma and prevention of postpartum breast engorgement.

Menopausal Syndrome—1.25 mg. daily, cyclically. Adjust dosage upward or downward according to severity of symptoms and response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day 5 of bleeding. If breakthrough bleeding (bleeding or spotting during estrogen therapy) occurs, increase estrogen dosage as needed to stop bleeding. In the following cycle, employ the dosage level used to stop breakthrough bleeding in the previous cycle. In subsequent cycles, the estrogen dosage is gradually reduced to the lowest level which will maintain the patient symptom-free.

Postmenopause—as a protective measure against estrogen deficiency-induced degenerative changes (e.g. osteoporosis, atrophic vaginitis, kraurosis vulvae)—0.3 mg. to 1.25 mg. daily and cyclically. Adjust dosage to lowest effective level.

Osteoporosis (to retard progression)—usual dosage 1.25 mg. daily and cyclically.

Senile Vaginitis, Kraurosis Vulvae with or without Pruritus—0.3 mg. to 1.25 mg. or more daily, depending upon the tissue response of the individual patient. Administer cyclically.

Abnormal Uterine Bleeding—(irregular, profuse, or prolonged uterine bleeding due to hormonal imbalance).

—*To stop bleeding*, 3.75 mg. to 7.5 mg. daily, in divided doses. Bleeding can usually be expected to stop within two to five days, b if it has not ceased within this time, an increase in dosage by 50 p cent or more is recommended.

—*For Cycle 1*—The dosage required to stop bleeding is cc tinued without interruption for 20 days. Otherwise, breakthrou bleeding will occur. During each of the last 5 to 10 days of estrog therapy, give an oral progestin. Expect withdrawal bleeding in t next two to five days after cessation of therapy.

—*For Cycles 2, 3, 4*—3.75 mg. daily, in divided doses, for 2 days beginning on the fifth day of bleeding, and a progestin give during the last five days of estrogen therapy. Expect withdraw bleeding in the next two to five days after cessation of therapy. Trea ment is usually given during three or four cycles.

Hypogenitalism—In an attempt to bring about sexual and s matic maturation, 2.5 to 7.5 mg. daily, in divided doses for 20 day followed by a rest period of 10 days' duration. If bleeding does n occur by the end of this period, the same dosage schedule is repeate The number of courses of estrogen therapy necessary to produ bleeding may vary depending on the responsiveness of the end metrium.

If bleeding occurs before the end of the 10 day period, begi a 20 day estrogen-progestin cyclic regimen as in Amenorrhea.

Amenorrhea—In order to reproduce the hormone pattern the ovary whereby there is bleeding from a progestational endom trium, begin a 20 day estrogen-progestin cyclic regimen wit PREMARIN, 2.5 to 7.5 mg. daily in divided doses, for 20 days. Durin the last five days of estrogen therapy, give an oral progestin. If bleed ing occurs before this regimen is concluded, therapy is discontinue and may be resumed on the fifth day of bleeding.

Mammary Carcinoma (for palliation in women with progressin inoperable or roentgen resistant disease who are more than 5 year postmenopausal)—Suggested dosage is 10 mg. three times dail for a period of at least three months.

Prostatic Carcinoma (for palliation when castration is not feas ible or when castration failure or delayed escape have not occurred —1.25 to 2.5 mg. three times daily. The effectiveness of therapy ca be judged by phosphatase determinations as well as by symptomati improvement of the patient.

Prevention of Postpartum Breast Engorgement—3.75 mg. ever four hours for five doses, or 1.25 mg. every four hours for five days

How Supplied: PREMARIN (Conjugated Estrogens Tablets, U.S.P

No. 865—Each *purple* tablet contains 2.5 mg., in bottles of 100 an 1,000.

No. 866—Each *yellow* tablet contains 1.25 mg., in bottles of 10 and 1,000. Also in unit dose packages of 100.

No. 867—Each *red* tablet contains 0.625 mg., in bottles of 100 an 1,000.

No. 868—Each *green* tablet contains 0.3 mg., in bottles of 100 an 1,000.

ROCKVILLE MARYLAND

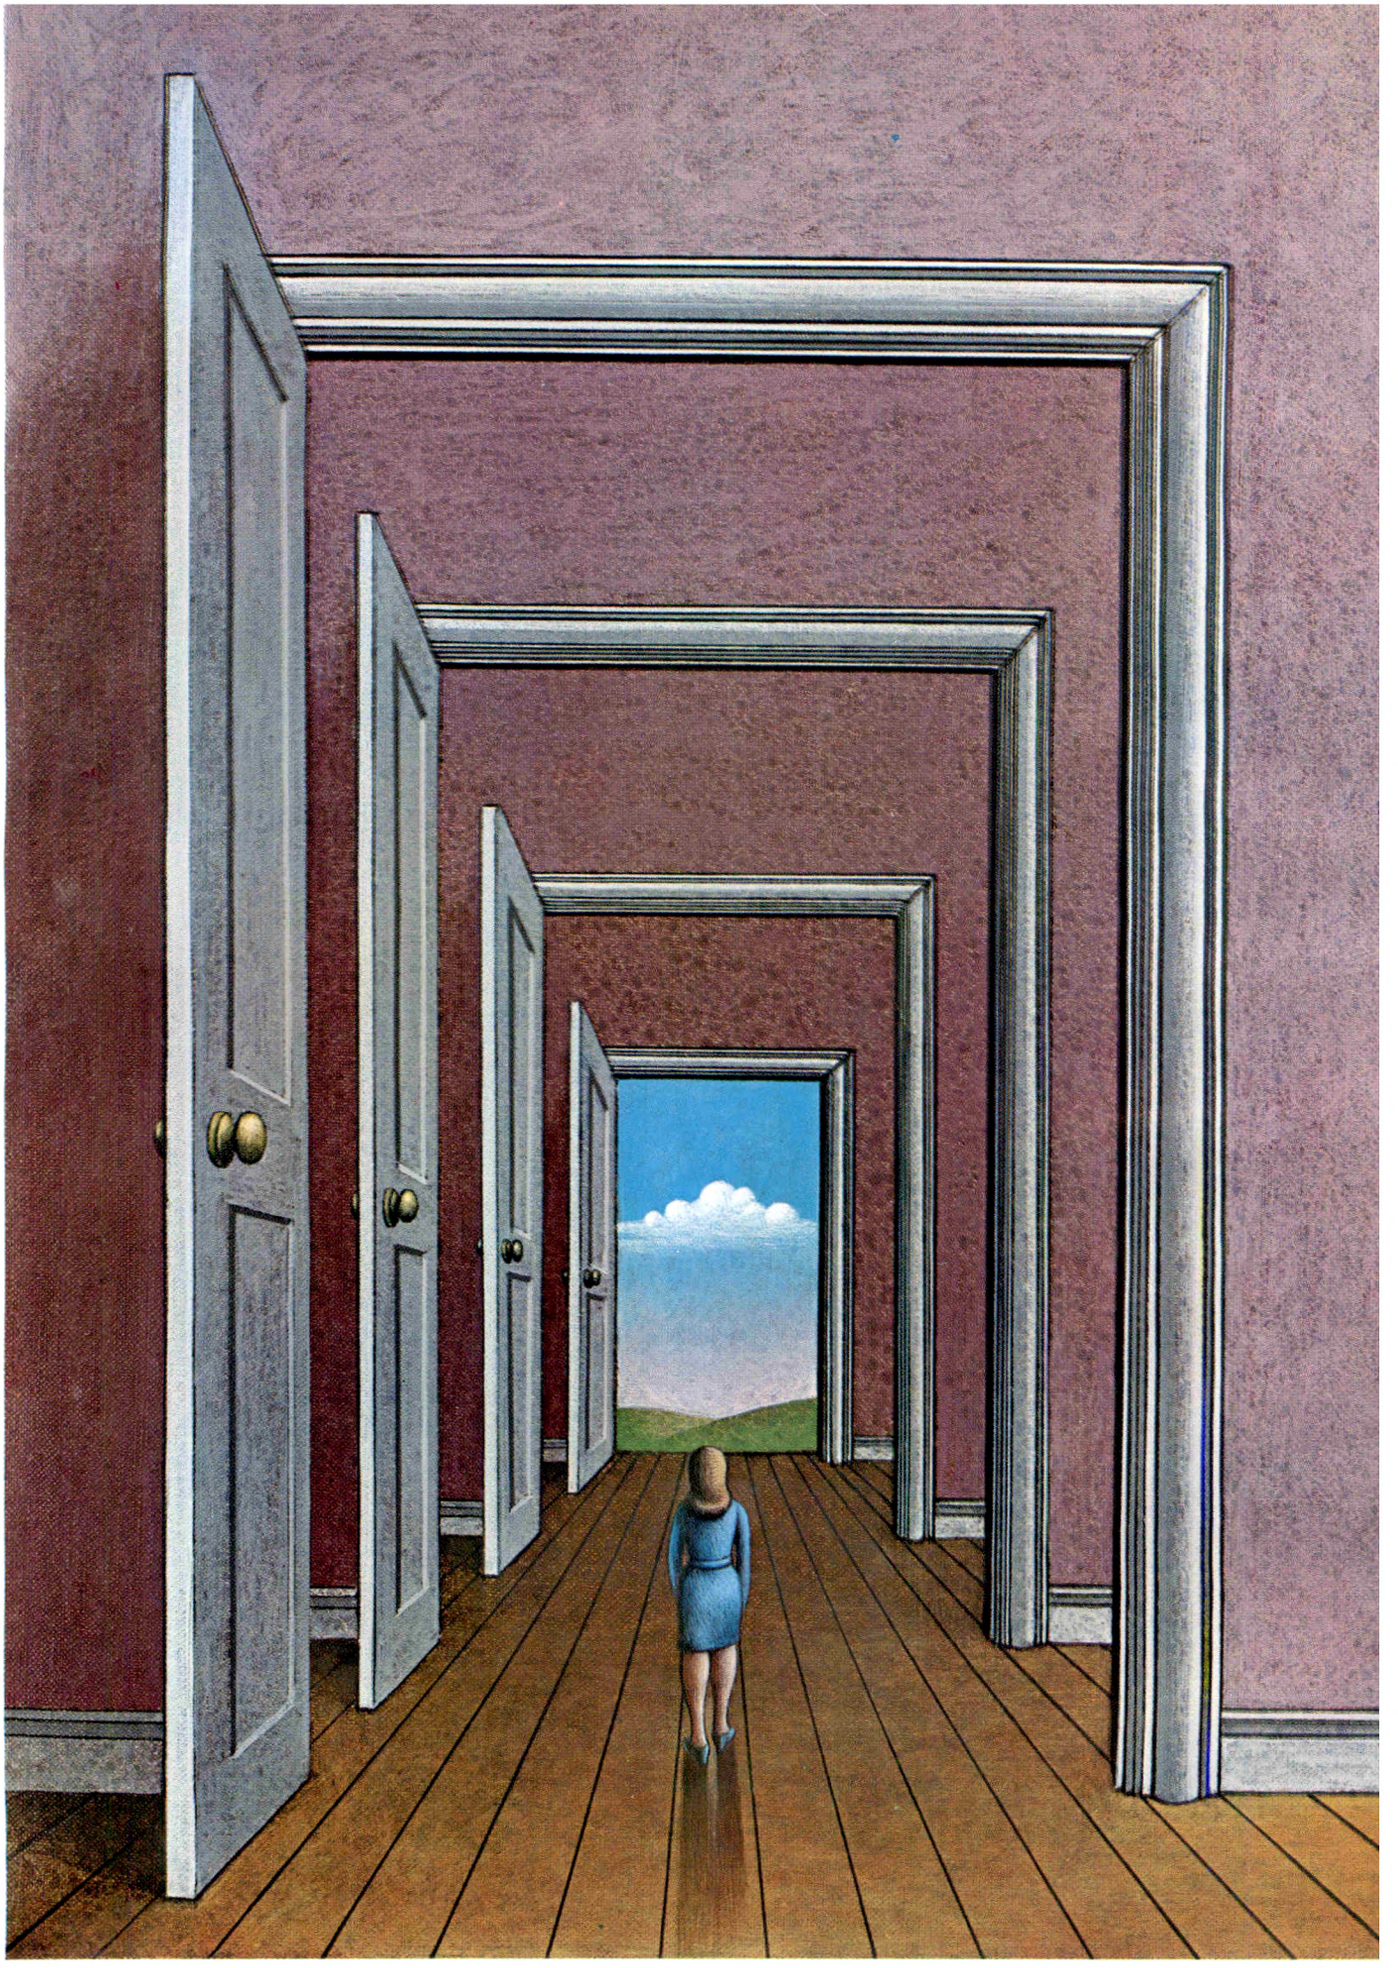
Child Psychiatrist

Director – Out-Patient Services $28,000-$32,100

(contract employment negotiable at attractive rates)

The Thistletown Regional Centre for Children and Adolescents, MINISTRY OF HEALTH, is located in northwest Toronto and is an affiliated teaching setting for the University of Toronto, approved for psychiatric training by the Royal College.

The Centre provides out-patient, day treatment, and residential treatment for emotionally disturbed children and adolescents.



The out-patient facility, besides providing screening for out-patient treatment for children and adolescents and their families, is committed to community consultation, education and research.

Applicants must have a licence to practise medicine in Ontario and certification in psychiatry (R.C.P.S. of Canada), or comparable specialist standing.

Please apply to: Clinical Director, 11 Farr Avenue, Rexdale, Ontario M9V 2A5.

Information on other medical positions may be obtained by writing to the above address.

ONTARIO
PROVINCE OF OPPORTUNITY

A HEAD START FOR THE CLINICALLY DEPRESSED PATIENT.

All tricyclic antidepressants take from one to four weeks before optimal antidepressant effect is seen.

Sinequan (doxepin HCl)—the newest tricyclic antidepressant—is no exception.

But, in that waiting period, Sinequan offers the clinically depressed patient both:

prompt sedative activity to begin relieving the sleep disturbances often characteristic of depression, and

marked antianxiety activity to help relieve the apprehension, tension, worry and fear that usually accompany depression.

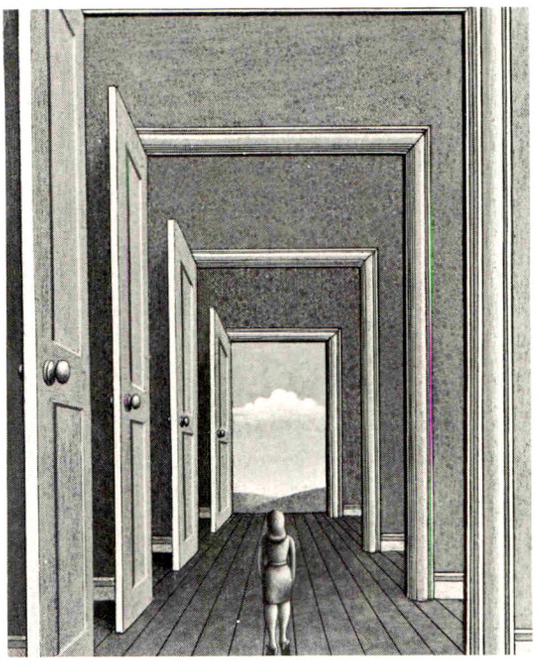
Further, the incidence of cardiovascular side effects with Sinequan is relatively low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) And Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses.

Prompt sedative activity. Marked antianxiety activity. Low incidence of cardiovascular side effects.

It's a head start for the clinically depressed patient.

THE NEWEST TRICYCLIC ANTIDEPRESSANT— WITH DIFFERENCES YOU CAN SEE.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules



Pfizer LABORATORIES DIVISION
PFIZER INC.

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

©1973, PFIZER INC.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules

THE NEWEST TRICYCLIC ANTIDEPRESSANT—WITH DIFFERENCES YOU CAN SEE.

BRIEF SUMMARY
Sinequan® (doxepin HCl) **Capsules**

Contraindications. Sinequan (doxepin HCl) is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan (doxepin HCl) is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan (doxepin HCl) has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan (doxepin HCl) in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan (doxepin HCl). The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan (doxepin HCl) has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan (doxepin HCl), however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan (doxepin HCl) can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan (doxepin HCl) does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

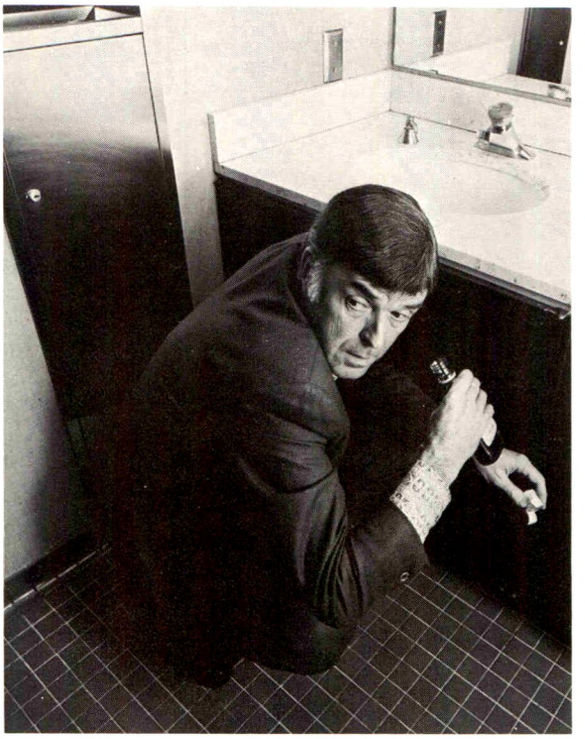
Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.



Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan (doxepin HCl) is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., and 50 mg. of doxepin in bottles of 100 and 1000.

More detailed professional information available on request.

Good Old Harry

No wonder he doesn't respond to treatment.

Harry is an alcoholic and he can't help it. Now there's a way and a place for you to get him the help he needs. So your treatment has a chance of success.

La Hacienda: The Last Resort.
La Hacienda is a pleasant, resort-style center in the Hill Country near Hunt, Texas. It offers a completely valid approach to the treatment of alcoholism.
Using individualized techniques developed in clinical practice, the full-time staff (both medical and psychological) employs bio-feedback, chemotherapy, individual, group and family psychotherapy, peer group interaction and other methods to reorient the alcoholic.
While his gross physical problems are undergoing treatment we attempt to alter the conditions and reactions which bring him to us in the first place.
At the same time, there are complete recreational facilities available: horseback riding, tennis, swimming, fishing and group activities with other patients and their families.

What To Do
A viable approach to alcoholism has long been needed. We believe we have one. Would you ask your nurse or secretary to write for complete information?

La Hacienda Hunt, Texas 78024
Telephone 512-238-4222

Please send me more information on the facilities, programs of treatment, and cost at La Hacienda. I understand there is no obligation.

The balanced approach in adjunctive drug therapy

Especially relevant in psychiatric practice

The role of anxiety as a psychodynamic force is generally acknowledged, although psychiatrists may differ as to its definition, origin and management. The intensity of anxiety may at times require adjunctive drug therapy for prompt relief of intolerable suffering; abatement of emotional tension, so that rapport and verbal communication may be expedited; and breaking down of stubborn resistances so that maladaptive behavior may

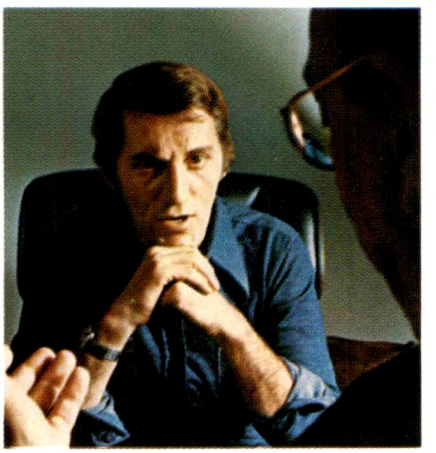
be examined.

But anxiety—in moderation an appropriate accompaniment of growth—need not and should not be diminished to the point of extinguishing its *signal* function. Drug and dosage should be selected so as to allow the maintenance and continuation of a reasonable amount of anxiety as an incentive to motivate participation in psychotherapy and to encourage problem-solving on the patient's own initiative. In this context, the so-called minor tranquilizers, in contrast to major tranquilizers, exhibit a well-tolerated, predominantly anti-anxiety action. Thus, when drug therapy of obstructive anxiety is required, a suitable minor tranquilizer is often recommended.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.



Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.,* operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of

Antianxiety action without exaggerated effect

Librium (chlordiazepoxide HCl) dosage meets patient needs

The benzodiazepines are regarded as among the safer and more effective of the antianxiety drugs available. Adjunctive Librium enjoys extensive use in the treatment of clinically significant anxiety. It should be employed flexibly, titrated to the degree of anxiety being experienced by the individual patient. The dosage schedule should have as its goal the maximum relief of disruptive anxiety; when that

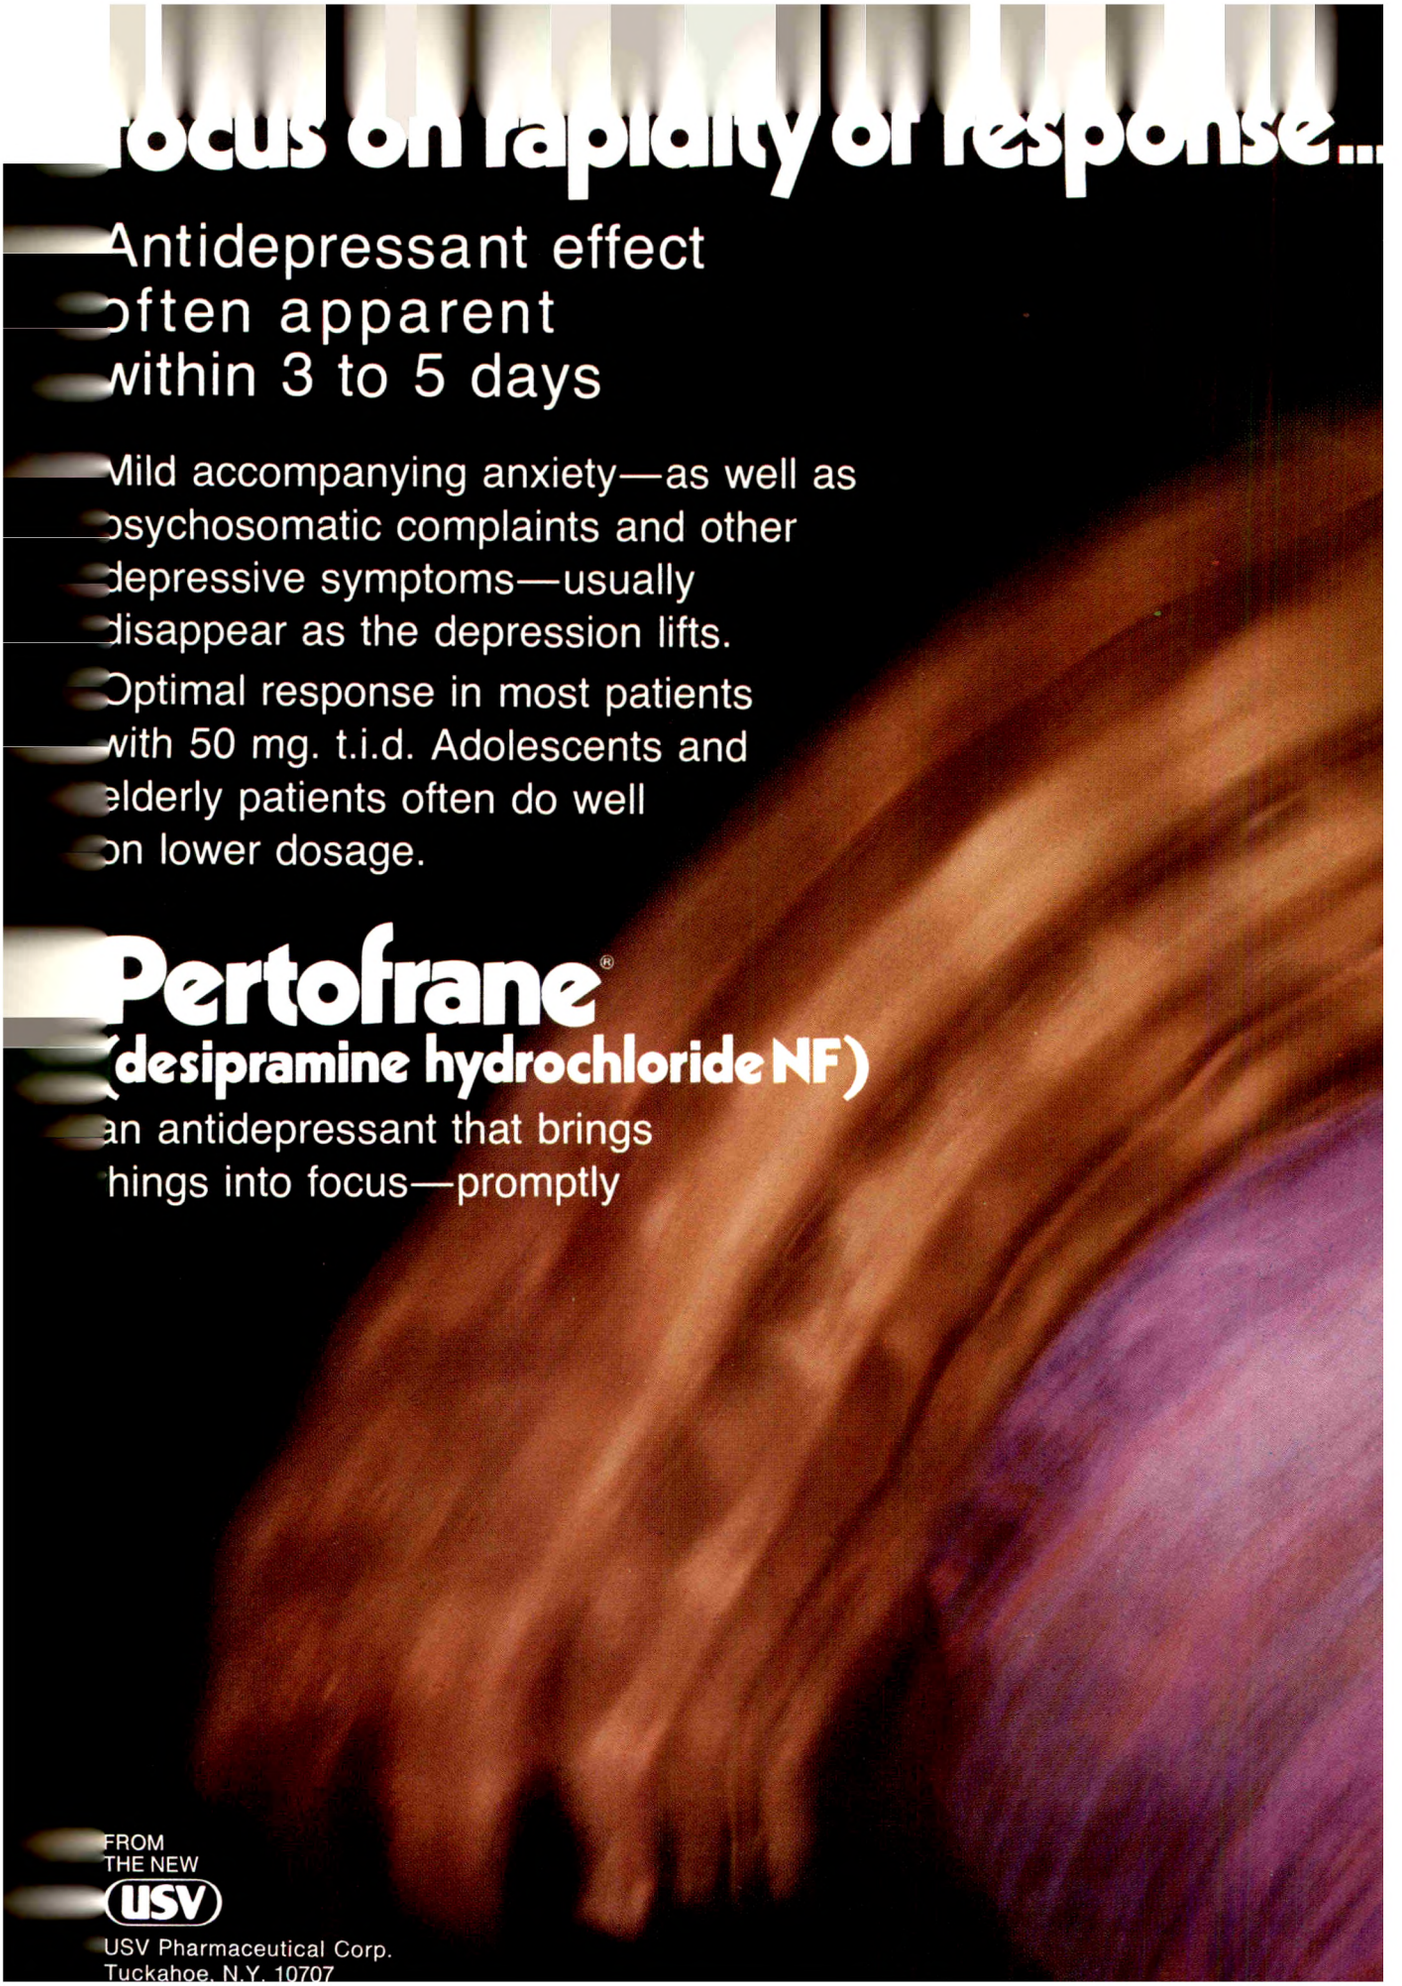
has been accomplished, Librium (chlordiazepoxide HCl) therapy should be discontinued. Experience has shown that Librium, in proper dosage, seldom impairs mental acuity or performance. (See Warnings section below.)

Drowsiness, ataxia and confusion are the most common side effects reported, most notably in the elderly or debilitated. Thus, Librium is especially valuable in treating anxiety in the neurotic ambulatory patient with daily responsibilities to fulfill. In most cases, Librium can promptly reduce excessive anxiety to less disruptive levels, making a rational approach to discussion of disturbing psychic material more possible, and encouraging a more positive resolution of the patient's emotional problems.

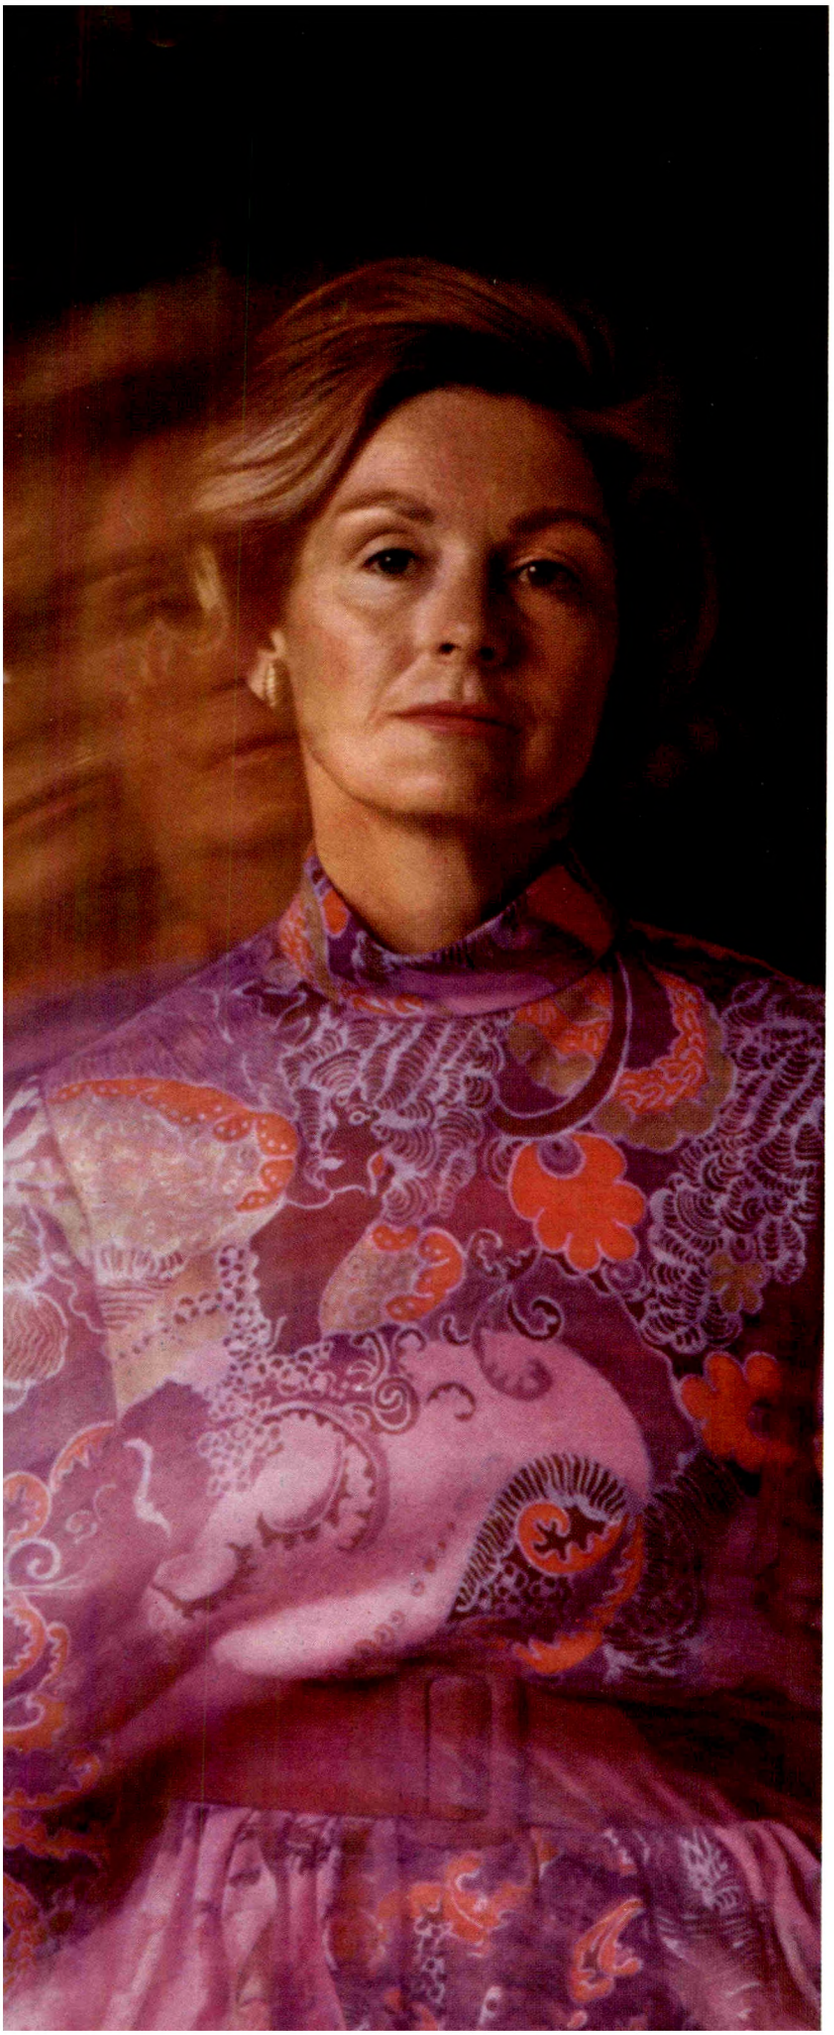
for control of inappropriate anxiety

Librium®
(chlordiazepoxide HCl)

10-mg, 25-mg capsules t.i.d./q.i.d.



ROCHE



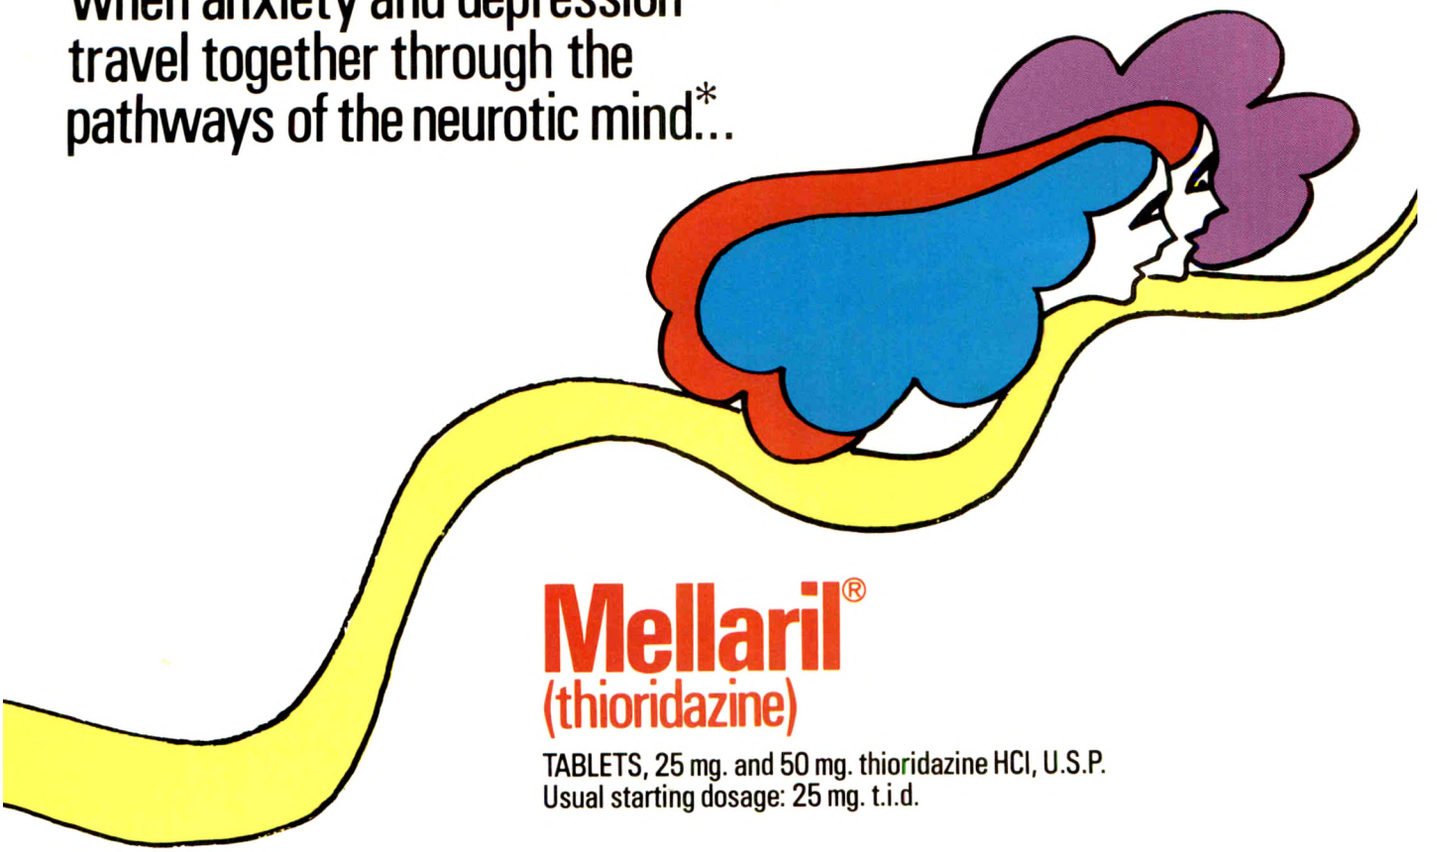
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido —all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

ocus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
FROM THE NEW
USV
USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707



Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

USV Pharmaceutical Corp., Tuckahoe, N.Y. 10707

when anxiety and depression travel together through the pathways of the neurotic mind*...

Mellaril®
(thioridazine)

TABLETS, 25 mg. and 50 mg. thioridazine HCl, U.S.P.
Usual starting dosage: 25 mg. t.i.d.

*Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified this indication as "probably" effective.
Final classification of the less-than-effective indications requires further investigation.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.
The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

Learning Disabilities: An Overview

BY LLOYD J. THOMPSON, M.D.

The expression "learning disabilities" is widely used and easily understood, but it may be applied to various handicaps. The author discusses the details of one particular handicap—reading disability—with implications that apply to the whole group in general. He emphasizes the concept that the fundamental basis of specific reading disability or dyslexia is usually found in inherent maturational lags rather than in brain damage or environmental influences. Although developmental lags do produce brain dysfunction, the author states the objections to the use of such terms as "brain damage" and "minimal brain dysfunction," which connote brain pathology. The concept of developmental lags is more accurate and more constructive.

THE TERM "learning disabilities" may be applied to a variety of difficulties encountered in the learning processes. It has wide usage, but perhaps it is too broad and not specific enough. The focus of attention in this dissertation will be concerned with a condition or syndrome characterized by specific difficulty in learning to read, spell, and write. Other difficulties in the realm of speech and hearing (word hearing) as well as motor disturbances, such as dyspraxia and hyperkinesis, are often present in the syndrome. Reading and spelling difficulties, however, are the presenting and most important symptoms. Not infrequently, secondary emotional and behavioral disorders mask the true nature of the handicap and may be the reason for referral.

Several names have been given to this syndrome. Among them are congenital word blindness, specific reading disability, specific language disability (SLD), developmental dyslexia, visuo-motor perceptive disorder, minimal brain dysfunction (MBD), neurologically impaired or handicapped child, brain-damaged child, and aphasoid child. This list is not complete, but a perusal of the literature under any of these titles reveals that in most instances we are talking about the same child or the same condition.

Because of this seeming confusion in terminology, the extensive bibliographies in five important books recently published on the subject were studied to see what designations were used by the authors cited. Out of 812 references, the wording in the titles fell under one of the following headings: reading disability = 504 (62 percent), dyslexia = 138 (17 percent), learning or language disability = 124 (15 percent), and brain damage or dysfunction = 46 (six percent).

It was gratifying to find the great preference for the simple, practical, and understandable term "reading disability." It was also gratifying to see "dyslexia" come in second, with "brain damage" running a poor fourth. Since I am medically oriented, I prefer the term "developmental dyslexia" or, for brevity, "dyslexia." In this word, "dys-" means hard or difficult, and "-lexia" is derived from the Greek word *lexikos*, which means "pertaining to words." Difficulty with words and the letters therein—whether spoken, written, or read—is the essence of dyslexia.

Regardless of the diagnostic label, there is general agreement that at least ten percent of children have some degree of specific reading disability. In 1965, the National Institute for Neurological Diseases and Blindness (1) stated that, from information obtained in this country and abroad, the figure of ten percent for specific dyslexia in children is "probably a reasonable estimate." Also, among these children, boys outnumber girls in a ratio of about five to one.

Without going into details about the symptomatology, it is obvious that these children must be two or more years retarded in reading, according to standard reading tests, but score higher in tests not involving reading. Their oral reading is apt to be word-by-word in a stilted manner, with hesitations and many guesses, and some may be nonreaders. In spelling, they reveal the earmarks of the handicap. They tend to spell "by ear"—showing

This paper was written at the invitation of the Editor.

Dr. Thompson is Clinical Professor Emeritus of Psychiatry, University of North Carolina, Chapel Hill, N.C., and Chairman of the Advisory Council of the Orton Society. His address is Kings Mill Rd., Chapel Hill, N.C. 27514.

their poor visual memory. There are reversals, omissions, and transpositions of letters. A "b" becomes a "d," an "m" becomes a "w," the word "was" may be "saw," and the word "girl" may be spelled "gril." A confusion in directionality and sidedness may exist, and there may be a tendency toward mirror-reading and mirror-writing. In addition to poor reading and spelling, these children may have delayed or imperfect speech, a poor ear for words, and clumsiness in handwriting or other movements.

When this condition is mentioned, questions as to cause invariably ensue. An attempt to provide answers will be made by starting with a review of the history of concepts.

HISTORY OF CONCEPTS

When W. Pringle Morgan (2), an English family physician, gave the first definitive description of reading disability in 1896, it was under the title, "congenital word-blindness." He said that the condition was "evidently congenital and due most probably to defective development of that region of the brain, disease of which in adults produces practically the same symptoms, that is, the left angular gyrus."

Immediately other English physicians, mostly ophthalmologists, published papers under the same title—all agreeing that the disorder must be due to some "agenesis" in the brain. James Hinshelwood, an ophthalmologist in Glasgow, continued these studies and, in 1917, published a book entitled *Congenital Word-Blindness* (3). He too maintained that the condition was due to a lack of development in the brain and was not caused by any disorder in the eyes. It is probable that all these early writers visualized some neuropathological changes in the brain that would someday be demonstrated.

It is interesting that, in 1891, Sigmund Freud (4), then a neurologist and not a psychoanalyst, stated in his monograph *On Aphasia:*

> There were cases of aphasia in which no localized lesion needed to be assumed and the symptoms could be attributed to an alteration of a physiological constant. Aphasia simply reproduces a state which existed in the course of the normal process of learning to speak and read (p. 55).

During the two decades from 1896 to 1916, other physicians in Germany, the United States, and elsewhere published articles on "congenital word-blindness," but no contributions from educators or psychologists could be found. Augusta Bronner (5), the psychologist in the first child guidance clinic, published her book, *The Psychology of Special Abilities and Disabilities*, in 1917. She gave attention to reading, spelling, and speech—reporting on observations in cases of reading disability with all the characteristics of dyslexia. She considered reading disability as being analogous to disabilities in other sensory and motor functions.

In 1918 Leta Hollingworth, an educational psychologist, wrote an article on "The Psychology of Special Disability in Spelling" (6). She expressed the opinion that this handicap is "the very fag end of the normal distribution of spelling ability." Then, in 1923 in her book, *Special Talents and Defects* (7), she discussed reading talents and defects. She recorded in detail her four-year study of a nonreader and said:

> We see therefore that non-readers, of general intelligence much above the minimal level required for reading, do learn to read when special training is given. This training may stress phonics (Schmitt), it may stress the motor and kinesthetic avenues of approach (Fernald and Keller), or it may stress visual perception (Gates). . . . It seems highly probable that the best method would be that wherein all avenues of approach are fully utilized (7, p. 89).

Concerning the cause, Hollingworth said the claim of Hinshelwood and others that it is due to a lesion or agenesis was "irreconcilable with facts known to psychology." Explaining this important observation, she stated:

> Cases where a generally stupid child is innately gifted with special ability to master the mechanics of reading, for example, are no doubt as frequent as cases where a generally capable child learns them with difficulty. The theory of specialized lesions or other faults of structure might cover disabilities, but would it cover special talents as well? (7, p. 52.)

In commenting on the pertinence of Hollingworth's question, I have pointed out elsewhere that, in cases of eidetic imagery, perfect pitch, or mathematical wizardry, we do not find hyperplasias in certain brain areas to account for the talent.

In 1925, the Research Committee of the Commonwealth Fund, chaired by William S. Gray (8), a noted authority on reading, published their report, *Summary of Investigations Related to Reading.* Out of 436 references in the report, there was one to Hinshelwood but none to the numerous other contributions from the medical profession. Reading retardation was recognized and numerous causes were listed, but "word blindness" or "specific reading disability" received no attention.

At that time, and later, Gray listed the following causes of reading retardation: irregular school attendance, malnutrition, poor health, nervous disorders, nationality, inappropriate methods of instruction, visual defects, auditory defects, and defects in brain tissue. Still later, Gray added other causes, but apparently he did not recognize the specific syndrome of dyslexia. Of course, any of the above-listed factors may retard reading and learning in general, but they are not likely to single out reading and spelling, or to produce the symptoms characteristic of dyslexia.

At this point in the history of concepts, it remained for Samuel T. Orton (9), an American neuropsychiatrist and neuropathologist, to shed further light on the problem. Starting in 1925, Orton continued to study and write about specific language disabilities until his death in 1948. He produced more than 30 articles on the subject, as well as his classic book, *Reading, Writing and Speech Problems in Children* (10). He disagreed with Hinshelwood and others about an agenesis or brain lesion and

proposed the concept that these specific language disorders are due to developmental lag.

Orton said that an important part of this delayed maturation is a failure to establish unilateral brain superiority with definite dominance on one side. The resulting confused laterality accounts for such symptoms as reversals of letters and words, poor directionality, mirror-reading, disturbances of "body image," etc. He also claimed that speech disorders, word deafness, distortions of time and space perceptions, and poor motor coordination were often a part of the syndrome. He recorded the existence of language disabilities, confused dominance, and other symptoms of dyslexia in the family histories of his patients. Working with Marion Monroe and Anna Gillingham, Orton was the first to develop a well-rounded program for remedial reading.

Not infrequently today we hear criticisms or outright rejection of Orton's explanations. It appears that some of the critics have not read Orton's writings, while others have taken points out of context. Usually, the opposition centers around what Orton said about confused dominance, and the objectors are thinking in terms of handedness rather than brainedness. They overlook the fact that many of the characteristics of dyslexia are the very symptoms of confused dominance.

Lauretta Bender, who had her training in psychiatry under Orton, has elaborated on many aspects of dyslexia (11). She continues to look upon dyslexia as being the result of maturational lag, with plasticity and the potentiality for further growth. Bender has had extensive experience with brain-damaged children and has been outstanding in pointing out the difference between brain damage and maturational lag.

Members of the medical profession in other countries have made notable contributions with concepts similar to those of Orton. Outstanding has been Macdonald Critchley, the eminent English neurologist. In his recent book *Developmental Dyslexia* (12), Critchley stated:

> Within the heterogeneous community of poor readers (slow readers, retarded readers), there exists a specific syndrome wherein particular difficulty exists in learning the conventional meaning of verbal symbols, and of associating the sound with symbol in appropriate fashion. . . . This syndrome of developmental dyslexia is of constitutional origin, and it is often—perhaps even always—genetically determined. It is unlikely to be the product of damage to the brain at birth, even of minor degree (p. 18).

OTHER CONCEPTS

It would seem that the above statement of Critchley might settle the issue, but there remain many divergent viewpoints and even resistance to recognition of such a specific handicap. It is not uncommon today to hear the opinion that if a child can't learn to read and spell, he must be quite dim or just isn't trying. Others who recognize the condition hold that the cause must lie either in brain damage or in the way the child was reared or taught. The possibility of developmental lag is overlooked or rejected.

For example, Rudolph Flesch, whose book *Why Johnny Can't Read* (13) was a best seller in the 1950s, held the concept that all reading retardation stems from the method of teaching. Flesch stated:

> Do you know that there are no remedial reading cases in Germany, in France, in Italy, in Norway, in Spain—practically anywhere in the world except in the United States? Do you know that the teaching of reading was never a problem anywhere in the world until the United States switched to the present method around about 1925? (p. 7.)

Many writers continue to claim that reading disability is attributable to emotional or environmental factors. Articles have appeared in the psychoanalytic literature under such titles as "learning disability" or "learning impotence." The first article in the *International Journal of Psychoanalysis* in which reading was the topic appeared in 1930 under the title, "Some Unconscious Factors in Reading" (14). The author, James Strachey, pointed out oral and anal factors that might be related to reading. He said that, in children with a reading disability, certain impulses are unstable or incompletely repressed, so that the act of reading threatens to bring about the release of these urges in their original primitive form. Strachey and later writers postulated that, in the child's unconscious, reading may have the significance of taking knowledge out of the mother's body; thus, fear of robbing her is an important factor for inhibition in reading.

Subsequent writers in the psychoanalytic field brought out other interpretations: relating reading disability to scoptophilia (peeping), to sadism, to special hostilities, to relation with one's mother or father, and to ego development. It is recognized that psychogenic factors may produce disturbances of vision, but usually this is in the form of hysterical blindness or tubular vision—not the reversal of symbols or the confused directionality found in dyslexia.

Writers from other disciplines continue to report on environmental influences as the cause of reading disability. The list given above in connection with the ideas of Gray covers the main areas of blame. They blame not only parents and teachers but a multitude of other factors.

Studies of deprived or disadvantaged children reveal that many of them are retarded in learning when they enter school and may never catch up. It is claimed, too, that most of these deprived children seemed to be on a par in development with other children during the first year or two of life. Some deprived children are labeled as having a reading disability because reading and spelling are the main subjects by which they are judged while, in reality, they may have a general learning retardation.

There is evidence that dyslexia has a causal role (often unrecognized) in school dropout, unemployment, and poverty. Therefore, many of the parents of today's deprived children may have been forced into poverty areas by their dyslexia, and so the handicap is passed on from generation to generation. It is doubly difficult for a dys-

lexic child to escape from the ghetto. Deprived children may suffer also from an "atrophy of disuse" during the optimum time of learning in the preschool years—thus producing a developmental lag. However, that this would be limited to the field of dyslexia seems unlikely. Let it be noted that, on the basis of general incidence, one in ten of the deprived children, as well as the mentally retarded children, would be expected to have some degree of dyslexia.

BRAIN DAMAGE CONCEPT

It is admitted that symptoms of dyslexia resulting from brain damage may occur in children, but this is very unusual. Dyslexia as a part of, or a kind of, aphasia due to brain damage was recognized long ago, but in most instances this happens in older people—often as a result of vascular accidents.

In recent years, there has been an increasing interest in the role of perinatal disturbances in brain damage. Poor nutrition and other abnormalities in the mother, birth trauma, anoxia, prematurity, infections in the newborn, and other disorders may produce brain damage. Kawi and Pasamanick (15) found that in 16.6 percent of 205 children with reading disability, there had been complications of the pregnancy, while in a control group of normal readers complications were found in only 1.5 percent. In the early literature on congenital word blindness, several writers mentioned prenatal factors and birth injuries when discussing causes. At the present time, books and articles are being published under the title "brain-damaged children," while the content is about dyslexic children. Here, too, perinatal disorders receive a large portion of the blame for the alleged damage, although later head injury and encephalitis may be called into account.

However, a point not emphasized before to my knowledge is that, if one side of the brain is damaged in the first year or two of life, the other side takes over the functions of the damaged one, especially with regard to language functions. Lord Brain (16) and others have attested to this developmental phenomenon. Moreover, Critchley (12) has stated:

> Specific dyslexia has nothing to do with perinatal trauma nor with fetal infection, fetal damage, anoxia, or icterus neonatorum. Of course, a patient with genetically determined dyslexia may also have a history of perinatal trauma, but this is a coincidental element in the case (p. 17).

Head injury often bears the brunt of blame for mental retardation and behavioral disorders, including delinquency. This is particularly true when parents want an answer that is not apt to create guilt feelings. That a fall from a high chair would single out for damage only the brain areas concerned with language functions is extremely remote.

Concerning encephalitis, let me cite my own experiences. In 1919, when I started my training in psychiatry at the Boston Psychopathic Hospital, epidemic encephalitis was rampant. We recognized the sequelae of this disease in children by their hyperkinesis, loss of inhibition, distractability, and gross behavioral problems. Some ten years later, after reading an article by Orton, I began finding specific language disabilities in some of these children who had had encephalitis. I collected 30 cases for study and later wrote an article entitled "Specific Disabilities in Children with Organic Brain Pathology" (17). At that time I was convinced that brain damage was the usual cause of specific language disabilities. However, with the passing of the epidemics, with more case studies, and with a broader outlook, I came to the conclusion that brain damage plays a very minor role in dyslexia. I had been guilty of thinking mainly in terms of psychogenic factors versus brain pathology, without consideration of constitutional factors in the realm of developmental lags.

Only sporadic and limited epidemics of encephalitis have occurred in the past four decades. Encephalitis accompanying infectious diseases of childhood, particularly measles, occurs in only a small number of cases. The elimination of measles will probably not diminish the incidence of dyslexia. Moreover, I have searched in vain to find a clear-cut case where the child had learned to read and spell before some alleged brain insult and then lost only this facility. Perhaps there are such cases, but they must be rare.

DIAGNOSIS OF BRAIN DAMAGE

In diagnosing brain damage, we consider the medical history, the neurological examination, the psychological studies, the EEG and X-ray findings, and clinical observations. It is contended, however, that positive findings in any of these fields may be due to developmental lags. The history of an illness or accident may be clear-cut, but the symptomatology is frequently nebulous and open to question.

The so-called "soft neurological signs" often come from developmental lags rather than from brain damage. Common to all infants is a positive Babinski sign, a tonic neck reflex, and other responses considered abnormal later on. Bender made the following observations:

> Children with severe reading disabilities show lags in neurological patterning or "soft neurological signs" also; they are awkward in their motor control and motility, and retain immature tonic-neck-reflex attitude for a longer time than other children do. Their motor tone is more variable; electroencephalographic patterns are of the dysrhythmic, immature type . . . and personalities are immature, impulse-ridden, and dependent, so that they are often taken for post-encephalitic, retarded, or schizophrenic children (11, p. 11).

Clinical psychologists may report certain test findings as indicative of organic brain disorder when, in reality, they come from maturational lag. Some of the responses on the Wechsler Intelligence Scale for Children are in this group, and the same may be true of primitive performances on the Draw-A-Person test. More specifically, some abnormalities on the Bender-Gestalt test may be

considered as evidence of brain pathology. According to Bender's own statement, however, in the performances of children with specific reading disability figures tend to be more primitive, more fluid, and full of movement of the primitive, vortical, whirling type; squared figures become rounded; dots are replaced by loops; diamonds are squared; oblique lines become vertical or sometimes even horizontal. She mentioned other observations, such as disorientation on the background and a tendency to close open figures. We know that she attributed all these distortions to maturational lag.

Concerning EEG patterns, many experts in the field agree that dysrhythmias and other deviations found in children below the age of six, or even eight, do not have the significance that they have later on. Here again, some clinicians look upon such variations as evidence of brain injury.

Among clinical observations in children, hyperactivity is receiving more and more attention. That hyperkinesis, even in outspoken degree, may be a manifestation of maturational lag rather than of brain disease has received only slight recognition. The majority of children pass through a definite stage of hyperactivity. Frequently, by the age of three hyperactivity may "simmer down," only to have a resurgence in the fourth year and continue into the early school years. Arnold Gesell stated:

> The 3-year-old is conforming. The 4-year-old is assertive and expansive. He bursts with motor activity: racing, hopping, jumping, skipping, climbing.... As an expansive 4-year-old he was constantly going out to meet his environment, making his thrusts in an almost harum-scarum manner (18, p. 56).

Gesell admitted that not all children conform to his age schedules and that hyperkinesis may persist through the early school years. R.L. Jenkins wrote on this topic:

> The hyperkinetic or hyperactive reaction is widely recognized in child psychiatry. It is disproportionately frequent before the age of eight and tends gradually to become less frequent and less prominent thereafter. It usually disappears by the middle teens.... There is no present justification for assuming that all cases are due to organic brain damage (19, p. 1032).

To the above statement, it can be added that many hyperkinetic children do not have a specific language disability, and not all dyslexic children are hyperactive. In fact, there is a growing tendency to consider hyperkinesis as a syndrome by itself.

One more item for consideration in relation to brain damage is the question of autopsy findings. I have heard physicians remark that someday a definite case of dyslexia will come to autopsy and then we shall know. With one person in ten, or even 20, having symptoms of dyslexia, thousands of cases have been autopsied, yet expert neuropathologists have reported no specific neuropathology related to developmental dyslexia. These same experts do not miss the lesions in older people who have had some form of aphasia, including dyslexia.

Recently, Norman Geschwind (20) demonstrated that an area which lies behind the primary auditory cortex in the upper surface of the temporal lobe (Wernicke's area) is larger on the left side in 65 percent of brains, but larger on the right side in 11 percent. This is an anatomical difference, not a lesion, and it appears to be genetically determined. It could be that, in the remaining 24 percent where no appreciable difference exists, an anatomical basis for language disability may be found.

The above observations about brain damage do not preclude the possibility that some biochemical disturbance may be basic in developmental dyslexia. It is generally accepted that nervous system activity depends on a chemical reaction—usually with one element present in the neuron and the other from without. Some disabilities of this type have been recognized. Several studies support the hypothesis that there is a biochemical process associated with learning, and with retention of information (memory). In color blindness, neurons in the cones of the retina fail to supply the element necessary to produce full color vision. The expression "lazy cones" suggests that elsewhere in the nervous system there may be "lazy neurons."

ANALOGOUS CONDITIONS

Color blindness, just mentioned, is analogous to dyslexia in many respects. It can be considered to be a developmental lag with an inherent biological basis. The newborn has no color vision and the disability "runs in families." There are varying degrees and kinds of color blindness. Rarely is it complete, wherein the person sees only black and white, or gray. About eight percent of boys, but less than one percent of girls, have some form and degree of color blindness—figures similar to those for the incidence of dyslexia. Rarely is it due to a brain lesion, and it is not caused by injury or disease in the eyes. It is not related to environmental or emotional influences. Let it be added that a color-blind person may improve his color vision through appropriate training and practice.

Analogous, too, are the cases of "word deafness" and extreme awkwardness (dyspraxia), both of which may be part of the total syndrome of dyslexia or may appear to be separate entities. "Tone deafness," with its varying degrees, suggests other disabilities in music, such as a poor sense of time or a shallow inner resonance for melody or harmony. Dyscalculia (disability in mathematics) is another example. Few people know about "taste blindness" for compounds of phenylthiocarbamide (PTC), which is genetically determined. Many speech disorders fall within the syndrome of dyslexia and, here again, the cause may not be found in emotional problems or in brain damage.

More and more evidence is being presented to show that autism in children is based on a combination of developmental lags. An outstanding feature of autistic children may be their great difficulty in understanding spoken words (word deafness), but they have many other lags, including those present in dyslexia. Perhaps their in-

ability to relate to other people stems from maturational lag. Without adding more examples, let it be stated that developmental lags are possible in all avenues of sensory input and in capacity for output in motor and emotional responses. There may also be lags in the inner elaborations between input and output.

HEREDITY

The use of the title "congenital word-blindness" by the early writers indicates that they considered the syndrome to be of congenital origin. Literally, "congenital" means acquired during development in the uterus or during birth, but several of these writers mentioned hereditary aspects and gave family histories to prove the point. Orton, from his first paper in 1925, repeatedly gave family histories and diagrams of family trees that showed the existence of language disabilities and confused dominance among the relatives.

Scandinavian researchers have given pertinent evidence as to the existence of genetic factors in dyslexia. Bertil Hallgren (21) of Sweden, in a study of 276 cases, found reading problems in one or more relatives in 88 percent of the cases. Moreover, Edith Norrie (22), in Denmark, and Hallgren studied twins—their combined total of pairs investigated was 45—of whom 12 pairs were monozygotic and 33 were dizygotic. Concordance was 100 percent in the former group and 30 percent in the latter. Hallgren concluded that developmental dyslexia follows a monohybrid autosomal dominant mode of inheritance. Knud Hermann (23), a co-worker of Norrie, stated in his book, *Reading Disability*: "It is highly probable that the specific pathogenic factor must be sought in heredity, whereby a predisposition to the underdevelopment of this function is transmitted in certain families by means of a dominant inheritance" (p. 179).

PROGNOSIS

With early recognition and adequate remedial reading instruction, a large majority of dyslexic children attain sufficient ability to read, for all practical purposes, but their typical spelling errors usually persist. Even without skilled tuition, some find their way around the handicap and improve as they grow older. This statement is not meant to condone a "wait and see" attitude. Without proper attention these children experience great frustration and often develop compensations of an undesirable type. There can be no doubt that unrecognized or untreated dyslexia plays an important role in school failure, school dropout, unemployment, poverty, and delinquency.

On the positive or optimistic side, Margaret Rawson (24) did a follow-up study of 20 dyslexic boys, all of whom had attended a private school where they had received remedial reading instruction according to the Orton-Gillingham system. All of them had gone on to college and, except for two, had gained degrees—several of them beyond the bachelor's degree level. Moreover, I have collected evidence (25) that several men of eminence probably had specific language disability. Among them were Thomas Edison, Harvey Cushing, Woodrow Wilson, William James, Albert Einstein, Lawrence Lowell, George Patton, Auguste Rodin, and Paul Ehrlich. There are others, some of whom are living, on my list.

In speaking about prognosis in developmental dyslexia, Critchley said, "There is no justification for anything less than optimism provided only that dyslexics are correctly diagnosed at an early age, and are granted without delay the services of special remedial teaching at the hands of sympathetic experts" (26, p. 121).

TREATMENT

Critchley's statement indicates that remediation of dyslexia falls mainly in the province of education. Early recognition is highly important, and it has been proven that tests and observations will usually reveal which children are going to have difficulty with reading when they enter the first grade. In addition to screening for physical health before school entrance, all children should be studied psychologically to identify their special abilities and disabilities. Much of this can be done by group tests, but tests that will reveal the probability of language difficulty should be included. For the dyslexia-prone child, the kindergarten can provide special activities and instruction that may be helpful.

All too frequently; dyslexia is not recognized until after the child has entered school, and sometimes not until he has gone to the fourth grade and beyond. To meet this situation, special classes and even special schools have been used. However, in addition to preschool screening, the ideal arrangement is to have ungraded classes with team teaching, wherein the language arts teacher is fully qualified in remedial reading and knows enough about dyslexia to be able to enter into the diagnostic process.

Details about remedial reading cannot be gone into here but the basic principle is the phonic approach, with emphasis on the alphabet, the sound and vision of letters, and their combinations in syllables and words. Visual learning is reinforced at the same time by other sensory modalities; the child says the letter or word aloud, traces it digitally, and may write it down. There is much more to remedial reading and, of course, the reading material, as well as the personality of the teacher, is important. The "talking typewriter," or even an ordinary typewriter, may be a helpful adjunct.

Psychotherapy may be needed, especially when secondary symptoms are troublesome, but it should be combined with remedial reading. A first step in therapy is an explanation—to the child and his parents—of the true nature of the handicap, making use of analogous examples such as color blindness or tone deafness, and making sure to dispel misconceptions about brain damage or parental fault. Of course, the school and the teachers may be at fault if they do not provide proper tuition.

Courses in speed reading are not for dyslexics. Al-

though often turned to, they only illuminate the handicap and increase the frustration. Motor exercises designed to improve coordination, while helpful in general, play no important role in correcting dyslexia. The Delacato program, with emphasis on "patterning" exercises, has been found to be of little direct benefit according to a study by the American Academy of Pediatrics (27). While confused laterality is common in dyslexia, attempts to change handedness, eyedness, or footedness are not indicated.

Drug therapy for learning disabilities is being advocated with increasing enthusiasm. The use of amphetamines to control hyperkinesis started in 1939, and its paradoxical action has not been adequately explained. If hyperactivity and distractability are diminished, a child can then better apply himself to any learning task. That amphetamines have any direct effect on reading ability is doubted. As noted before, hyperkinesis may be one of many manifestations of maturational lags and sometimes occurs along with dyslexia. The use of amphetamines to control hyperkinesis in a dyslexic child so that he can get on with his learning may be indicated in some cases, but certain studies have shown that the drug is beneficial to less than one-half of all hyperkinetics. Also, amphetamine habituation does occur, and there is no proof that children are entirely immune to such habit formation.

COMMENT

Although psychiatrists and other members of the medical profession may not be involved in the direct treatment of learning disabilities, they should be knowledgeable in this field. They should be able to participate constructively in the diagnosis and recommendations for treatment of these handicaps. Finally, it is urged that due consideration be given to the role of inherent maturational lag, so that the diagnosis does not rest solely on differentiation between environmental factors and brain damage.

Early Stress and Later Response to Separation in Rhesus Monkeys

BY LAURENS D. YOUNG, M.D., STEPHEN S. SUOMI, PH.D., HARRY F. HARLOW, PH.D., AND WILLIAM T. MCKINNEY, JR., M.D.

The hypothesis that separation in early life predisposes one to later psychopathology was tested using two groups of rhesus monkeys of similar age. The experimental group had undergone the stress of early life separation and confinement in a vertical chamber. The experimental animals responded to separation and reunion with increased self-mouthing, self-clasping, huddling, and rocking. The control group responded to separation with increased locomotion and responded to reunion with increased contact clinging and proximity behaviors. The implications of these findings are discussed.

SEPARATION EXPERIENCES in early life have long been regarded in psychiatric theory and practice as traumatic events that can predispose individuals to psychopathology later in life (1, 2). In general the validity of this relationship has not been questioned (3). However, while psychiatric evidence obtained through a retrospective anamnesis may well have established the importance of separation in early life to the psychological functioning of the adult, it has also been criticized for making it appear that certain sequelae proceed inevitably from a given event (4). We know, for example, that not every individual who experiences a difficult separation in infancy eventually develops serious psychopathology. It therefore behooves investigators to regard the relationship between adult psychopathology and trauma in early life as a hypothesis and to attempt to establish experimentally whether such a relationship exists. Some have suggested that separation in early life may "leave scars" that sensitize individuals to adverse reactions to later separation (5). The experiment reported in this paper is a controlled laboratory investigation of this hypothesis in nonhuman primates.

Various efforts have been made in recent years to supplement the retrospective method in human beings with other types of studies. For example, Sethi obtained information on both childhood separations and separation experiences occurring within six months prior to the onset of depression in 116 patients (6). He found that 63 percent of the patients who scored high on a clinical inventory of depression had had a history of antecedent separation, whereas only 14 percent of those who scored low on the inventory had had such an experience. On the same inventory, 67 percent of the patients who scored high had had a separation experience before the age of 16, whereas only 37 percent of those who scored low had had such an experience. Finally, 44 percent of the patients who scored high had had *both* early and recent separation experiences, compared with 11 percent of those who scored low.

In a group of 120 hospitalized patients, Levi found significantly more incidents of separation before the age of 16 in patients who actually attempted suicide than in those who did not attempt suicide (7). The data in this study also suggested that there was a significantly higher incidence of separation experience before the age of seven in persons who actually attempted suicide than in those who only had an impulse to commit suicide.

Hill and Price compared 1,483 depressed patients with 1,028 nondepressed patients (8). They found a significantly higher incidence of loss of father by death before the age of 15 in the depressed group. A number of additional studies have found some positive relationship between the early loss of a parent and psychiatric disturbance in later life (9–11).

Birtchnell (12), in comparing 500 hospital admissions with a matched sample of 500 persons from the surrounding community, found a higher incidence of parent death before the age of five in the patient population. He also found a higher than expected incidence of recent parent death in the hospital population (13). Birtchnell failed to find a preponderance of early or recent parent death in patients with a diagnosis of depression, although these events were significantly higher in the subpopulation with *severe* depression (14). Moreover, his statistics indicated that early and recent parent death contributed to the incidence of suicide attempts in patients, independently of a diagnosis of depression (15).

Not all studies have indicated a positive relationship between early life events and psychiatric disturbance in later life (16–18). For example, Hudgens compared 40 depressed patients with 40 closely matched controls and failed to show any differences in the incidence of stressful events in early life (19).

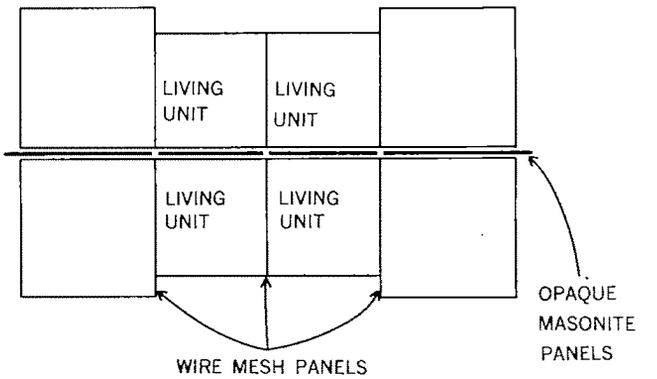
The authors wish to express their appreciation to Elaine Moran and Robert Eising for their assistance with this project.



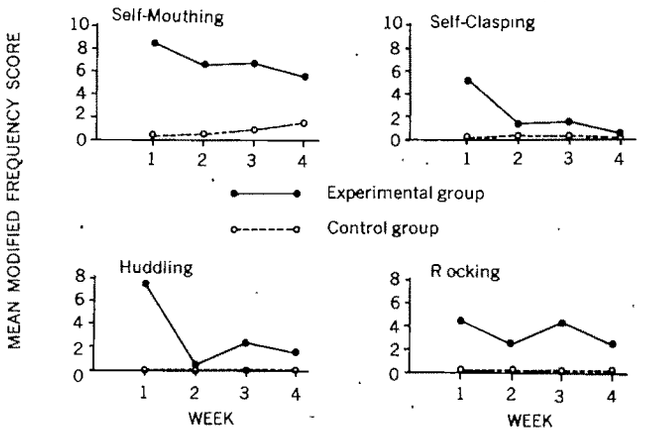
Other studies have indicated that the relationship between early life events and psychopathology is very complex. Paykel and associates have suggested that events of an "exit" type contribute more significantly to depression than do "entrance" events (20). A recent study by Cadoret and associates (21) comparing two groups with unipolar depression showed that, although there was no significant difference between the two groups in the actual incidence of such separation experiences as death, divorce, or separation of the parents, those patients whose onset of symptoms occurred before age 40 and who had certain other distinguishing characteristics showed a higher incidence of the *reporting* of a loss.

Many clinicians have established through intensive direct observation that dramatic behavior changes can occur in infants and young children who have undergone a major separation experience (22–24). Freud and Dann (25) studied a group of six children over a three-year period after their release from a concentration camp. Initially the children showed a high degree of attachment to each other and hostility toward the adults around them. It was only after several months that more typical child-child and child-adult behaviors began to appear. Spitz described a syndrome of "anaclitic depression" occurring in 19 of 123 children between six and 11 months of age in a foundling home (26). He postulated that this syndrome was caused by separation from the mother and could become irreversible if it was not remedied by replacement of a suitable mother or surrogate.

Bowlby characterized the human infant's response to maternal separation as occurring in three stages: "protest," "despair," and "detachment" (3). Such observations imply that loss in infancy might affect the adult individual's response to subsequent separation, but such follow-up studies are rare and give scattered results. Bowlby and associates (27) collected data on 60 children aged six to 14 hospitalized in a tuberculosis sanitarium for periods of several months and found very little indication of severe emotional impairment in adult life. Other investigators, however, on the basis of observations of institutionalized children (28, 29), have found evidence for lasting intellectual and emotional impairment that persisted into adolescence. Such studies are confounded by a complexity of variables, such as the age at separation, parent-child relationships before and after the separation, and the relative conditions of the environments (30).

In recent years some effort has been made to circumvent the difficulties involved in human clinical studies by creating animal models for human psychopathology (31–33). Nonhuman primates provide a useful model for some aspects of human behavior because of their closeness to man, their tendency to form close social bonds, the existence of a fund of knowledge about their social behavior, and the availability of suitable laboratory methods for well-controlled longitudinal studies. Early work using rhesus monkeys established the importance of the infant's tie to its mother (34). Experimental separation from the mother (35) produced a syndrome in rhesus monkeys that closely resembled the behavior of human infants described by Spitz and Bowlby. Replication of the separation experiment with other species has demonstrated a similar response to separation, with some species variation (36, 37). In the rhesus monkey, the species used in this study, the "protest" stage is characterized by frequent cooing vocalizations and increased locomotion. This stage is followed by a period of "despair," consisting of decreased locomotion and increased self-clasping, self-mouthing, and huddling. The final stage of "detachment" described in humans by Bowlby has not yet been reproduced in monkeys.

FIGURE 1
Cage Assembly of Experimental Living Unit



Separation from the mother before one year of age and confinement in a Harlow vertical chamber is a method that has proved effective and reliable in producing abnormal behavior in infant monkeys (38, 39). For example, monkeys 45 days of age placed in this chamber exhibit markedly abnormal behavior on removal. They are socially withdrawn, have low levels of locomotion, and exhibit high levels of self-mouthing, self-clasping, and huddling behavior.

This study attempts to assess whether such stress in early life predisposes rhesus monkeys to pathological behavior later in life when they are subjected to separation stress. Subjects who had early life separation and vertical chamber confinement were compared with subjects who had had normal laboratory rearing. The hypothesis was that these "traumatic" events early in life would predispose the subjects to more severe reactions to the stress of separation later in life.

METHOD

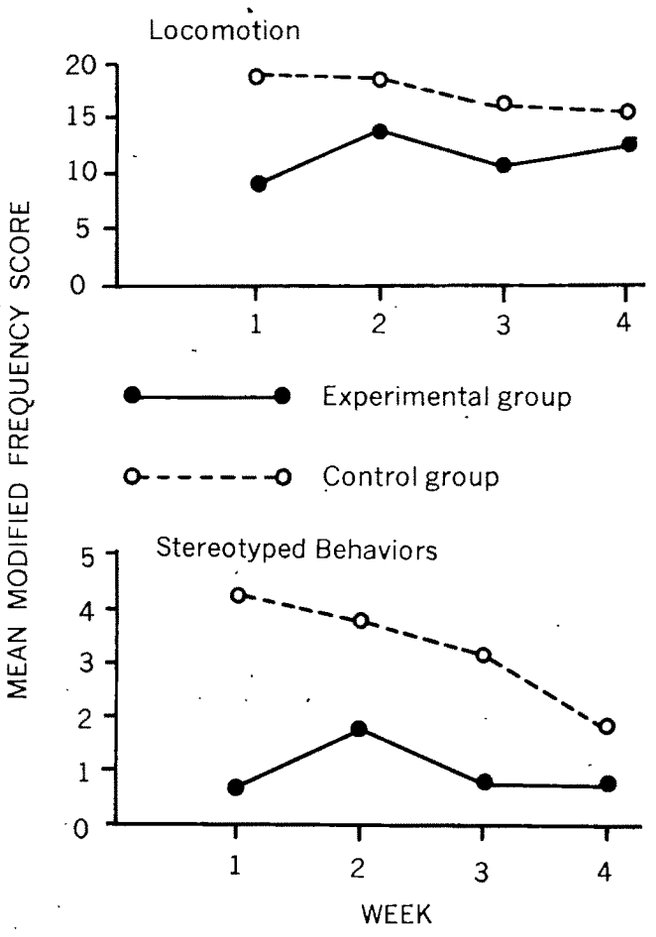
Two groups, each consisting of four rhesus monkeys almost two years of age, were used as subjects. The two groups had had different rearing experiences. The monkeys in the experimental group had been taken from their mothers at birth and housed in individual cages with cloth surrogates. They had been permitted two hours of peer experience per day throughout the first year of life. Between five months and ten months of age each subject

FIGURE 2
Self-Mouthing, Self-Clasping, Huddling, and Rocking During Separation

was placed in a vertical chamber (40) for 30 days of profound environmental isolation. Following the period of internment each subject was returned to its living cage. Beginning at one year of age, the experimental subjects were housed as a group in a wire mesh cage, where they remained until the start of the present experiment. In summary, they had undergone experimental early life separation and the stress of confinement in a vertical chamber early in life.

At the start of the experiment the subjects in the control group were approximately the same age as those in the experimental group. They had been reared with their mothers for the first month of life. From one month until one year of age they had lived in a large cage complex with their mothers, with two hours of daily social interaction with each other. From one year of age until the start of the experiment they were housed together without their mothers as a group of four. Therefore they were matched with the experimental group in terms of age and peer experience after one year of age but differed regarding early life separation and vertical chamber experience.

During the present experiment each group of four monkeys was housed together in a large experimental living unit, a series of cages joined end-to-end, in which the animals could both live and be tested without being moved to a strange environment. The cage assembly is shown in figure 1. The spaces between the cages permitted insertion of wire mesh partitions that divided each large unit into four smaller cages. When the wire mesh panels were removed, the open ends allowed free access through the entire length of the unit. Opaque masonite panels were placed between the two large cage assemblies to prevent visual and tactile communication between the experimental and control groups.



The experiment was divided into two time periods: a four-week period of baseline observation, called the preseparation period, followed by a four-week experimental period. During the preseparation period observations were made on four days each week while the monkeys had free access to each other and to their half of the entire cage assembly.

The experimental period was further divided into separation and reunion conditions. The subjects were housed individually 23 hours per day under the separation condition and were together one hour per day under the reunion condition on the days of observation. They were housed individually all day long on the remaining days.

During the separation condition the wire panels were slid into place so that each monkey was separated from his peers. Observations were made four times per week on each of the monkeys housed in this manner. Under the reunion condition the wire mesh panels were removed so that the monkeys had free access to each other and the full cage assembly. Observations were also made on the monkeys in this condition four times per week.

Behavioral observations were made on each animal for a five-minute period each morning on four days per week during the preseparation period. Similar five-minute observations were made of each subject as it was individually housed in the morning during the separation period and in the afternoon during the reunion condition. The five-minute observation periods were divided into 20 15-second intervals. Any of the operationally defined behavior categories that occurred during these intervals were scored as modified frequencies, that is, as the number of

FIGURE 3
Locomotion and Stereotyped Behaviors During Separation

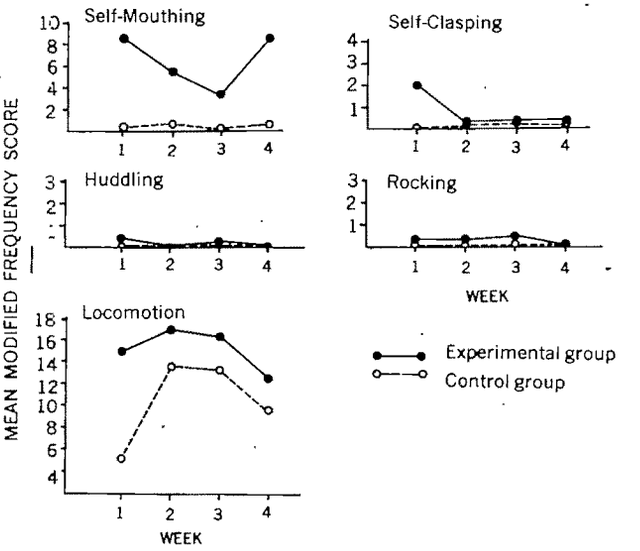
15-second intervals in which a behavior occurred. The use of this scoring system has been described previously in some detail (41). Operational definitions of the behavioral categories used are given in appendix 1.

For each animal a weekly mean modified frequency score was calculated thus: the total weekly number of responses of a given subject in a given category divided by four, the number of observation periods in the week. Behavior categories that consistently had scores of zero or nearly zero were omitted from the remaining analysis. For each of the remaining categories a two-way repeated measures analysis of variance was performed for each of the three experimental conditions (preseparation, separation, and reunion). The prior rearing condition (experimental versus control) was the independent variable. Time blocks of two weeks for the preseparation condition and blocks of one week for the separation and reunion conditions were the repeated measures. The .05 level of confidence was designated as the criterion of statistical significance for each analysis. In those cases in which significance was reached or almost reached and more than two means were involved in the calculation of the mean square, a Duncan New Multiple Range test was used to compare the means with each other (42).

RESULTS

Preseparation Condition

Four behavioral categories showed significant group effects during the preseparation condition. These were self-mouthing, locomotion, stereotyped behavior, and yielding. None of the other categories showed significant differences between the groups during this condition. The experimental group showed consistently higher levels of self-mouthing ($p < .01$). The control group showed higher levels of locomotion, stereotyped behavior, and yielding ($p < .05$).



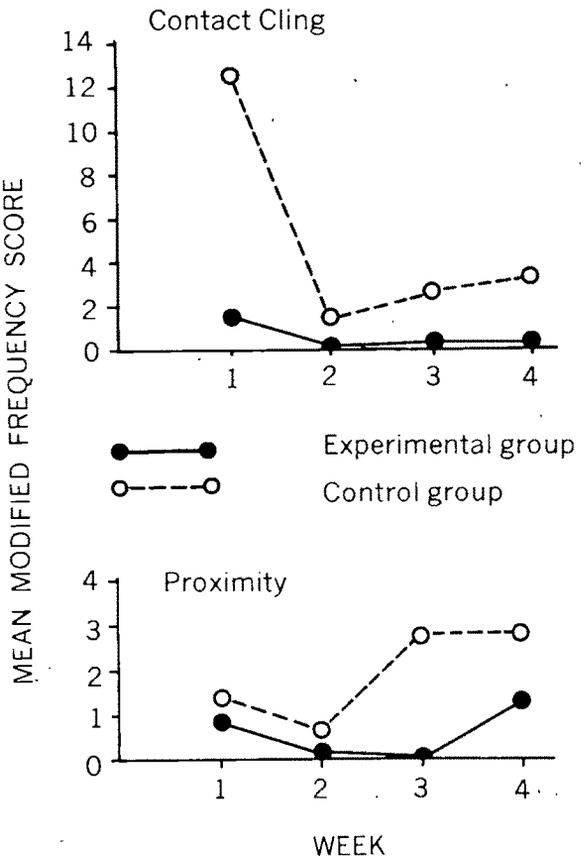
Separation Condition

Under this condition, since the animals were alone, six social behaviors logically could not occur: yielding, contact cling, proximity, social exploration, social sex, and play. These were, therefore, excluded from the analysis of this condition. The experimental group showed significantly higher levels of self-mouthing and huddling ($p < .05$) during separation. The experimental group also showed higher levels of two other behaviors that did not reach significance—self-clasping and rocking. For self-mouthing the difference between the groups for the first week was significant by the Duncan test ($p < .05$). For rocking, the between-group differences for all four weekly means were significant by the Duncan test ($p < .01$). These differences are shown in graphic form in figure 2.

Self-clasping, huddling, and rocking were almost never shown by the controls. On the other hand, the control group showed higher levels of locomotion ($p < .05$) and stereotyped behavior ($p < .01$) during the separation condition. These differences are illustrated in figure 3.

FIGURE 4

Self-Mouthing, Self-Clasping, Huddling, Rocking, and Locomotion During Reunion



Reunion Condition

There were significant group differences for the following four behaviors, with the experimental group showing higher levels during reunion: self-mouthing and locomotion ($p < .01$) and rocking and self-clasping ($p < .05$). The experimental group also displayed some huddling, which was absent among the controls. The behavior categories for reunion in which the experimental group showed higher levels are illustrated in figure 4. The group means for proximity and contact cling behaviors are illustrated in figure 5. During reunion the control group showed significantly more contact clinging and proximity behaviors than the experimental group.

DISCUSSION

The results of this experiment indicate that several behavioral distinctions can be made between a group of four two-year-old rhesus monkeys with a history of early life separation and vertical chamber confinement and a group of monkeys raised with their mothers and with peers. Throughout all conditions of the experiment—preseparation, separation, and reunion—a higher rate of self-mouthing behavior was observed among the experimental group than among the controls. This tendency toward self-orality has been noted before in rhesus monkeys raised without mothers from birth (43). Self-mouthing is also commonly observed in infant rhesus monkeys immediately following vertical chamber confinement (44). The observation of high rates of this behavior under varying experimental conditions in older monkeys who have had separation and chambering experiences very early in life, and the virtual absence of self-

FIGURE 5
Contact Cling and Proximity During Reunion

mouthing in monkeys of similar age who have not had such experiences, indicates that self-mouthing may be a stable behavioral trait related to early history.

The experimental imposition of conditions of separation and reunion revealed further behavioral differences between the two groups that appeared to be labile and dependent on the condition. Separation conditions caused the experimental animals to react with dramatic increases in self-clasping, rocking, and huddling, behaviors that were almost never seen in the control group. Such "despair-like" responses are similar to those reported in infant macaques undergoing maternal separation and vertical chamber confinement for the first time (44). The pattern resembles the stage of "despair" described by Bowlby. In some respects, therefore, our imposition of the stress of separation from peers in these older monkeys appears to have "unmasked" or at least intensified a response to stress that probably developed in very early life.

The group of monkeys raised with mothers and peers, on the other hand, showed none of the "despair-like" behaviors of the experimental group. These animals responded to separation with an increase in locomotion and stereotyped behavior. This response is similar to that observed in monkeys reared with mothers and peers who are separated for the first time at three years of age (45). The dramatic response in the control animals was observed under reunion conditions. On being allowed access to each other again after separation, the control group showed higher levels of contact clinging and proximity behavior than the experimental animals. This response has been reported previously in animals undergoing reunion after separation, and it might be regarded as a typical pattern of response to reunion for juvenile monkeys raised with mothers and peers (46). The experimental group, on the other hand, did not respond with such high levels of these "closeness" behaviors, but rather with a higher level of locomotion than the control group. It appeared that separation and chambering inhibited their capacity to respond to reunion in the usual way.

The above findings are best viewed as tentative, we hope provocative, and suggestive for further research. Additional work is necessary to extend the generality of our hypothesis. Certainly, however, the marked tendency of rhesus monkeys with a history of maternal separation and vertical chamber isolation early in life to respond to separation with behaviors remarkably like those displayed in early life is supportive of our hypothesis. It remains to be seen whether such behaviors will appear in animals with similar histories at more advanced stages in life. In future studies, more emphasis will be placed on the important effect peer groups have on the final behavioral response, and appropriate measures will be taken to control for this. Work is currently under way in our laboratory to determine to what extent other forms of separation stress will tend to recapitulate the "despair-like" behavioral responses in monkeys with a history of early life stress.

Certainly it is difficult to analogize directly to human behavior but our findings may point to fruitful areas for exploration. The remarkable similarity of the syndrome produced in older monkeys by chambering to that displayed when they were young should cause us to look for behavioral similarities in follow-up data on adults who suffered clearly traumatic manifestations as a result of separation or environmental deprivation in childhood. Few studies of this sort have been reported (30). Our data indirectly support previous studies in human subjects that show a relationship between human psychopathology and the combination of separation in early life and recent separation (6, 12–15).

It appears that early and later life experience can combine to have a powerful influence on primate behavior, in man as well as monkeys. What remains to be decided is not whether such a relationship exists but how it comes to be.

APPENDIX 1

Definitions of Behavioral Categories

Self-mouthing: Oral contact with any part of the body except the genital area, excluding biting.

Self-grooming: Discrete self-directed picking and/or spreading of the fur.

Self-biting: Specific, vigorous, self-directed biting.

Self-clasping: Firm manual or pedal clutching of self, excluding the genital area.

Passivity: Maintaining a static position for a minimum of three seconds with no other simultaneous behavior.

Huddling: Self-enclosed fetal-like position incorporating any or all patterns of self-clasping, self-embracing, or lowered head.

Rocking: Repetitive, nonlocomotive backward and forward movement.

Vocalization: Coo—drawn-out, dove-like cry in a variety of pitches; screech—high intensity vocalization resembling a scream.

Yielding: Oriented movement or withdrawal by an animal submitting or ceding area to another animal.

Stereotyped behavior: Identical movements maintained in a rhythmic and repetitive fashion for at least three cycles; scored independently and noninclusive of locomotion.

Locomotion: Ambulation of one or more full steps.

Environmental exploration: Any tactual or oral exploration of the physical surroundings.

Proximity: Standing within three inches of another monkey for a period of three or more seconds.

Contact cling: Maintaining gross body contact for an indefinite period of time.

Tardive Dyskinesia: Side Effect or Not?

BY JOHN P. CURRAN, M.D.

The author briefly reviews the literature on the relationship between the administration of phenothiazines and the appearance of tardive dyskinesia. He presents three case reports which illustrate that the relationship is not understood well enough to justify labeling tardive dyskinesia as a side effect of phenothiazines.

WITHIN SIX YEARS after the introduction of the phenothiazines, three neurological side effects were clearly recognized to result from the administration of these medications: dystonia, akathisia, and parkinsonism (1). While these side effects differed somewhat in sex distribution and in age of onset, all had in common the property of disappearing when the phenothiazine in question was discontinued. It was this feature which led to their identification as side effects.

Currently there is less agreement about the significance of the "tardive dyskinesia" syndrome, i.e., a characteristic array of involuntary movements, which allegedly appears late in the course of treatment with phenothiazines. These movements especially, but not exclusively, involve the perioral region; hence the syndrome has been termed "perioral dyskinesia." Many clinical reports have been published, such as the series of patients described by Faurbye and associates (2). Two reviews of the literature are also available that discuss, among other things, the more controversial aspects of this syndrome. Since most observers agree that patients demonstrating the involuntary movements in question can be identified in selected populations, and that there is no effective treatment as yet (3, 4), most of the controversy involves questions of etiology, prevalence, and outcome. There is wide agreement that tardive dyskinesia is "irreversible."

A number of factors have been implicated in the onset of this movement disorder (2, 3). Brain damage from lobotomy or from multiple courses of electroshock treatment (EST) is cited as a cause. A small percentage of cases are said to be acutely and directly precipitated by even a few EST treatments. On occasion the syndrome appears to occur "spontaneously" in elderly patients who do not have a history of shock treatment, lobotomy, or phenothiazine ingestion. The role of phenothiazines in the genesis of this syndrome is especially unclear. Crane, who has published extensively on the subject, notes that the syndrome may appear during, after, or upon resuming treatment. Kline states that he has observed the syndrome to occur after treatment with nonphenothiazine medications, such as antidepressant drugs with anticholinergic activity or amphetamines (4). Elsewhere it has been suggested that an occasional case of acquired hepatocerebral degeneration may be mistaken for tardive dyskinesia (5). Finally, a recent report has suggested that disruption of dental proprioception may be a factor in those cases in which perioral symptoms are especially prominent (6).

One criterion of a side effect is its temporal relationship to a specific treatment modality. Perhaps the most intriguing aspect of the tardive dyskinesia syndrome is that, when a clear link to administration of phenothiazines has been observed, the relationship is paradoxical: the syndrome appears or becomes worse when phenothiazines are discontinued. Faurbye and associates commented on this in passing (2), and Kennedy published a case report that clearly illustrates this puzzling feature of tardive dyskinesia (7). Crane and associates also refer to this phenomenon in other papers (8–11).

In this report I will describe three outpatients, all of whom experienced the onset of the syndrome shortly after discontinuing moderate doses of phenothiazine derivatives, which each had been taking for at least one year. These cases are presented to illustrate that the link between tardive dyskinesia and phenothiazines is not clear-cut enough to be termed a side-effect relationship.

CASE REPORTS

Case 1. This 47-year-old divorced woman appeared at the Mental Health Center of Hennepin County General Hospital on April 17, 1969, after not having been seen for several years, complaining, "I couldn't hold my job because I couldn't stand still." She stated that she had stopped all of her medications (15 mg. of trifluoperazine and 150 mg. of chlorpromazine per day) one month previously and that involuntary movements had appeared one week later and had become progressively worse. Eventually she was fired: "They said I was too nervous."

Her medical history was unremarkable, but she did have a history of mental illness dating from 1950, when she first experienced hallucinations and delusions. She was treated with several courses of EST. Eventually she was hospitalized at Rochester State Hospital in Minnesota, where her course was stormy. After 28 or more ESTs did not produce improvement, a modified Grade IV prefrontal lobotomy was performed in December 1952. There was initial improvement, but once again she became difficult to manage. Forty-eight more ESTs followed. Finally, she was started on reserpine and was eventually discharged in November 1955.

Dr. Curran was formerly associated with the Department of Psychiatry of Hennepin County General Hospital, Minneapolis; he is currently in private practice at 527 Medical Arts Building, Minneapolis, Minn. 55402.

She was first seen at Hennepin County General Hospital in February 1963, complaining of "an inferiority complex." Despite constant ideas of reference and persecution she had managed during the previous six years to marry and to hold a job. It was felt that her condition represented post-lobotomy paranoid schizophrenia. She was started on 24 mg. of perphenazine per day, then 12 mg. of trifluoperazine per day, but she did not reappear until I interviewed her in April 1969.

The mental status examination revealed a tall, thin, not unattractive woman with a tense, strained expression, complaining of involuntary movements. Vigorous rocking to-and-fro, which could be voluntarily controlled, was accompanied by simultaneous tapping movements of the feet. No movements of the arms or mouth were present. She was pleasant, cooperative, not paranoid, and lucid, and she demonstrated insight regarding why she was fired. My initial impression was that she was not psychotic but was experiencing the tardive dyskinesia syndrome. The possibility of acquired hepatocerebral degeneration masquerading as tardive dyskinesia was ruled out by testing her hepatic functioning.

I decided to resume her medications despite the absence of psychosis to see whether the movement disorder could be controlled, starting with 4 mg. of trifluoperazine per day. When no change was noted by April 22, the dosage was increased to 10 mg. per day. Eight days later she reported improvement. Trifluoperazine was increased once more to 15 mg. per day. On May 7, she demonstrated no involuntary movements during the interview, but was observed pacing beforehand. At her request, 100 mg. of chlorpromazine per day was added and was subsequently increased to 150 mg. per day. On May 27 she reported that she had returned to work. Occasional restlessness of her left leg was present, and during the latter stages of the interview she began to rock. On June 23, nine weeks after I first saw her, she described complete recovery. At this point, she was still taking 15 mg. of trifluoperazine as well as 150 mg. of chlorpromazine per day. During the interview she initially rocked, then sat upright and quite still. Her posture was graceful rather than rigid. She appropriately requested sleeping medications. Occasional sucking motions of the lips were present, but no jaw movements. She appeared completely free of the presenting movement disorder. Ten months later her condition was unchanged, with approximately the same dosage of phenothiazines.

The diagnosis of paranoid schizophrenia seems unquestionable, although it was remarkable how cooperative the subject was during her treatment, and how reliable her self-observations were. One cannot rule out the possibility that she was simply experiencing prepsychotic anxiety and agitation, since perioral movements were not a prominent part of the picture and the rocking was quite similar to that occasionally seen in acutely agitated patients. On the other hand, the chief complaint of involuntary movements, the foot-tapping associated with the rocking, and the absence of complaints of anxiety and agitation all pointed to tardive dyskinesia as the more likely diagnosis.

Case 2. This 66-year-old widow was seen in the outpatient department on August 1, 1969; she had stopped her medications two months previously because of her religious convictions as a Christian Scientist. She was brought in by relatives who noted that she was delusional again, expressing the belief that she was going to be imprisoned for filling out income tax forms incorrectly.

Her history indicated that in 1964, following the death of her husband, she tried to commit suicide by walking into a river. She was committed to Anoka State Hospital in Minnesota in April 1965, after a history of auditory hallucinations was elicited; she was diagnosed there as having an involutional depression. In March 1966, she was discharged on unknown medications; she worked thereafter as a night clerk in a board-and-care home. An exacerbation of her illness occurred in August 1966, and she was diagnosed as having chronic schizophrenia upon admission to Hennepin County General Hospital. She was returned to Anoka State Hospital and was discharged in January 1967 on a daily dose of 1000 mg. of chlorpromazine, 20 mg. of trifluoperazine, and 2 mg. of benztropine mesylate. She was seen in the medication clinic here eight months later and her medications were renewed. She was not seen again until she was brought in by her relatives.

The mental status examination (by John Docherty, M.D.) revealed an elderly woman who admitted to impaired memory. Her affect was flat. A marked perioral dyskinesia was present. After her admission, other observers noted perioral dyskinesia with clipped speech, athetoid movements of the tongue, akathisia, and tasikinesia.

On August 6, she was seen by me in consultation. I noted that she was alert, waited for cues, and appeared to be somewhat shy and retiring. She manifested unsteadiness of her torso, a tendency to caress her hair and face in a stereotyped way with her left hand, and constant mouth motions without protrusion of her tongue. No rigidity or tremor was present. A diagnosis of acute psychotic reaction was made, as well as tardive dyskinesia. Her liver function was tested and was unremarkable.

Administration of 225 mg. of chlorpromazine per day was begun, but was stopped in favor of 6 mg. of haloperidol per day when sedation and hypotension were noted. On August 11, occasional involuntary mouth motions were present, as well as distinct unsteadiness of the trunk. Two days later she appeared to be pleasant, agreeable, and well oriented, with some restlessness of arms and torso still present. By August 19, all signs of psychosis had disappeared and she was also free of involuntary mouth or body motions. She was discharged to Anoka State Hospital, where she stayed for two months. Thereafter she was seen at bimonthly intervals in our outpatient department; she was taking 100 mg. of nortriptyline hydrochloride, 6 mg. of haloperidol, and 2 mg. of biperiden per day. On January 12, her mental status examination was unremarkable.

Several observers recognized what seems to have been a typical example of the tardive dyskinesia syndrome, the waxing and waning of which was clearly but inversely related to the administration of antipsychotic medications.

Case 3. This 49-year-old man was a regular visitor to the outpatient department when I began to follow him in 1968.

In 1957 he was described as experiencing psychotic episodes. In 1965 he spent nine months at Anoka State Hospital, where he was diagnosed as having a schizophrenic reaction because of psychosis, agitation, and restlessness. Administration of phenothiazines resulted in a state of complete inactivity that responded to six ESTs. He was discharged on 300 mg. of thioridazine per day and was referred to our outpatient department, where he was seen at approximately three-month intervals over the following years. Motor restlessness was noted frequently. Eventually he lost his job because he was "too slow." His signature on a release of information dated January 3, 1968, was quite small and cramped.

When first seen by me on October 5, 1968, he was taking 400

TABLE 1
Summary of Case Reports

Mental status	Nonpsychotic	Psychotic	Nonpsychotic
Movement disorder	Trunk, extremities	Face, trunk, extremities	Face, trunk, extremities

mg. of thioridazine and 2 mg. of benztropine mesylate per day and demonstrated motor restlessness. On April 23, 1969, I noted very slight akathisia and I recommended that he reduce his thioridazine to 300 mg. per day. The benztropine mesylate was also discontinued. On July 16 I described him as follows: "would sit stiffly in his chair . . . at first no involuntary movements . . . later rocks to-and-fro . . . a fine tremor of his right thumb . . . on one occasion crosses both arms rather restlessly." My impression was that he had both akathisia and stiffness as motor side effects of the thioridazine. The patient, however, did not wish to decrease the thioridazine further. Three months later several observers felt he manifested definite parkinsonism. Again it was recommended that he lower his drug dosage since there was no evidence of a psychosis; he reluctantly agreed to decrease the thioridazine to 200 mg. per day.

On November 5, 1969, motor restlessness without noticeable movement of the tongue or lips continued to be present. For the first time the possibility was raised that, in view of the persistence of motor restlessness despite halving the dosage of thioridazine, we actually were dealing with tardive dyskinesia rather than akathisia. When this was explained to the patient and further dosage reduction suggested as a possible means of confirming the diagnosis, he pleasantly refused. Nonetheless, on January 28, 1970, there was a marked change in his appearance. Quite prominent constant champing of his mouth with frequent partial protrusion of the tongue was present. There was marked continuous rocking to-and-fro associated with twisting and writhing of the torso. He also kept crossing and uncrossing his arms, and he stood up once or twice during the interview. When this dramatic change was commented upon, the patient remarked that he had decided to reduce his thioridazine to 100 mg. per day after all. After some discussion, it was decided to increase the dose to 200 mg. per day.

Two weeks later he was observed to shift his weight from foot to foot while waiting for the interview. When seen he initially demonstrated slight protrusion of his tongue, then was quite relaxed and at ease for several minutes. Prominent oral motions and rocking motions were not seen at all during this time. Toward the end of the interview he began to manifest slight crossing and recrossing of his arms, as well as a slight rocking to-and-fro. I thought that he was much better. It was decided to continue the thoridazine at 200 mg. per day.

One month later he demonstrated throughout the interview continual motion of his tongue but did not protrude it. Rocking but not writhing of the torso was also present. Crossing and recrossing of his arms occurred every few minutes. His mental status was otherwise unchanged. He refused to increase the thioridazine dosage as recommended.

Although the diagnosis of schizophrenia was made at Anoka State Hospital, the patient manifested little evidence of schizophrenia and no evidence of psychosis while he was under my observation. On the other hand, he clearly manifested a combination of neurological findings, most of which were probably drug-induced, although idiopathic parkinsonism cannot be ruled out. Careful and repeated observations document the appearance of perioral phenomena, as well as a marked increase in a dyskinesia of the trunk and extremities after his phenothiazine load was reduced.

These involuntary motions were partially relieved by his resuming a higher daily dosage of thioridazine. Presumably they would have completely disappeared had the patient agreed to resume thioridazine at its former level.

DISCUSSION

Clinically these three patients are different in some respects from the typical patient in whom the syndrome is noted. Usually the affected person is a demented, elderly, chronic, institutionalized woman. None of the present subjects conform to this pattern, as table 1 indicates. Also, the duration of the abnormal movement before its recognition usually is unknown. Perhaps these differences, along with early identification of the syndrome, account for the "reversibility" described above when the drug loads were restored to their former levels. In one case the abnormal movements were completely abolished, while substantial improvement occurred in the other two.

Some of the controversy about tardive dyskinesia is probably due to two factors: 1) lack of recognition and 2) prematurely labeling it as a side effect.

Regarding lack of recognition, my own experience in working with chronic, often difficult inpatients (12) is that the behavioral repertoire of such patients becomes more impoverished the more they are hospitalized, whether or not the underlying disease process is "functional" or organic. The chronic patient simply cannot give you a history. Alertness and tenacious recording of ongoing behavior are required to distinguish among

TABLE 2
*Frequency of Dyskinesia in Three Experimental Groups**

*Data from Crane (9).

simple agitation, learned "schizophrenic mannerisms," and psychotic disorganization and to separate these from choreoathetoid or dyskinetic motor movements. It is not unfair to say that the average chronic inpatient is probably not the beneficiary of this degree of clinical skill. It is conceivable that the untutored observer might mistake the dyskinetic movements for agitation or mannerisms or psychosis and treat them with phenothiazines, thus establishing a spurious correlation for the later investigator.

Several years ago, B.C. Schiele and I made a preliminary study[1] of the population and records of a state mental hospital to determine the incidence of the tardive dyskinesia syndrome and to get some idea of what role phenothiazines have in the genesis of these unusual movements. We found that the records of this institution were completely inadequate to the task of making a retrospective determination of the causal relationships among drugs, symptoms, and behavior. How many reports have been drawn from similarly incomplete records?

Ignorance of tardive dyskinesia also suggests that the results of "drug holiday" research studies may need to be reconsidered. If it is true that some cases of tardive dyskinesia are precipitated or exaggerated by withdrawal of neuroleptics, then the incidence of relapse may be overestimated in experimental versus control groups. This is a significant risk when one considers that the incidence of tardive dyskinesia when drugs are abruptly reduced or stopped ranges from 12–14 percent according to Crane (8, 11) to 30 percent in the experience of Hershon and associates (13). The latter are also concerned about the problem of nonrecognition.

A series of papers published by Crane and associates cannot be criticized for lack of clinical or, for that matter, research skills (8–11). Indeed, this work has been a major factor in the elucidation of tardive dyskinesia. One hesitates to comment upon such a distinguished body of work. I believe, however, that Crane's identification of tardive dyskinesia as a side effect of neuroleptic drugs has led to some difficulty in his interpreting the results of otherwise meticulous work (14).

This is reflected in his study of the incidence of tardive dyskinesia in two groups of subjects who were given high (80 mg.) or low (16 mg.) doses of trifluoperazine, as well as in a control (placebo) group (9). Observations were collected at baseline, after a six-month trial of the different regimens, and also after all groups had resumed routine treatment for six months. (This averaged out to about 300 mg. per person of chlorpromazine or its equivalent for all groups.) The results are summarized in table 2.

As would be expected if tardive dyskinesia is a typical neuroleptic side effect, a number of cases appeared after six months of treatment: 12 in the high-dose group and six in the low-dose group (10). However, Crane is at a loss to explain certain other findings—for example, the increase in dyskinesia among high-dose subjects after they had been returned to routine treatment for six months. One would expect a decrease, since the subjects in this group went from the equivalent of 1600 mg. per day of chlorpromazine (assuming trifluoperazine is 20 times as potent as chlorpromazine) to about 300 mg. per day of chlorpromazine or its equivalent. Yet at least four new cases appeared. The placebo group is also puzzling, but especially relevant in view of the case reports above, since at least seven new cases developed after the subjects were switched to a placebo; some of these cases disappeared when routine treatment was resumed. Crane noted that his data are difficult to interpret rationally.

A subsequent study by Crane and Naranjo produced less ambiguous results (11). Using factor-analytic techniques, they isolated three clusters of involuntary motor movements in patients treated with phenothiazines. One cluster did not correspond to any recognized neurological entity. A second corresponded to pseudo-parkinsonism, while the third closely resembled tardive dyskinesia. They then studied the effects of phenothiazine withdrawal in a sample of patients over a six-month interval. The pseudo-parkinsonism cluster decreased in magnitude but the tardive dyskinesia cluster increased. No significant changes were noted in a control group that was treated routinely for six months. Among their conclusions was that these results supported previous observations that the reduction or removal of neuroleptics may uncover or magnify tardive dyskinesia.

Hershon and associates, employing the same research methodology, reached the same conclusions (13). Both groups of workers avoided defining this paradoxical find-

[1] This study was never published but is summarized by Ettinger and Curran (5).

ing as a side-effect relationship:

Yet Crane recently stated without qualification that tardive dyskinesia is a side effect of phenothiazine treatment (14). My belief is that such an interpretation of the evidence is not only premature but misleading as well. It might lead the physician to conclude that phenothiazines should not be administered or should be withdrawn in cases of tardive dyskinesia. This would be unfortunate since, as demonstrated above, *withdrawing phenothiazines aggravates the syndrome.* Moreover, such a viewpoint neglects several reports from England that the syndrome can be reversed with thiopropazate, a phenothiazine structurally similar to chlorpromazine (15–17).[2]

It seems to me that the evidence is not sufficient to establish tardive dyskinesia as a side effect of neuroleptics. That a drug can produce a syndrome both upon administration and withdrawal seems absurd, but the evidence indicates this is so. Perhaps as the contribution of brain damage to the genesis of tardive dyskinesia is defined this contradiction will be resolved. It should be noted that the recent systematic studies of Crane and Naranjo (11) and Hershon and associates (13) were carried out in selected populations that were free of organic brain damage. Perhaps studying this variable, which is widely recognized to be important in the production of tardive dyskinesia, will provide more intellectually satisfying answers.

[2] I have tried thiopropazate in two other cases of tardive dyskinesia for up to three months and have found that this is so. Unfortunately, the drug is no longer marketed in this country.

Language and Thought Content in Acute Psychosis

BY FRANK E. REILLY, M.D., MARTIN HARROW, PH.D., AND GARY J. TUCKER, M.D.

Twenty-three acute schizophrenic inpatients were given a standardized 15-minute "free verbalization" interview during the acute phase and again during partial recovery. During the acute phase, patients tended to get lost in a vivid, overwhelming flood of details, whereas later they took more distance and were not as overinvolved, even when discussing the same subjects. Over time there was a shift to future concerns and a renewed interest in interpersonal relationships and responsibilities. Patients became more organized and coherent over time.

THE STUDY OF mental illness has become extremely sophisticated in almost every aspect but, as elegant as the new techniques have become, one of the most perplexing and fascinating elements of mental illness remains the free verbalizations of the acutely psychotic patient. This type of clinical material was used most extensively by Bleuler (1) and other early clinicians, and it was found fruitful in many formulations about the nature of schizophrenic disorders. While verbal material such as this has been reported for individual patients (2), and their thinking has been explored with specific tests, there have been surprisingly few systematic studies of the changes in the verbal behavior of acutely psychotic patients at specific time points in their illness. The last taped study of looseness of associations of the speech of schizophrenics in a large sample was done 19 years ago using a group of *chronic* schizophrenics before the phenothiazine era (3). Bleuler's examples of schizophrenic speech, absorbing as they are, were also taken from a chronic population.

The present investigation represents an attempt to systematically study and analyze the free speech of a sample of *acute* schizophrenics at two time periods: 1) on admission to the hospital or at the height of the acute episode and 2) seven weeks after hospital admission (partial remission). It is designed to answer the following questions: 1) Are there any characteristic patterns in the free verbalizations of the acute schizophrenic patient at the height of his disorder? 2) Does the verbal content of the acute psychotic patient change with partial recovery?

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors were all formerly with the Department of Psychiatry, Yale University School of Medicine, 333 Cedar St., New Haven, Conn. 06510, where Dr. Reilly is Instructor in Psychiatry and Dr. Harrow is Associate Professor. Dr. Tucker is now Associate Professor of Psychiatry, Dartmouth Medical School, Hanover, N.H.

METHOD

Subjects and Setting

The subjects were 23 acute schizophrenic patients interviewed during their first and seventh weeks of admission to the psychiatric inpatient division of Yale-New Haven Hospital (4, 5). The sample consisted of young acute schizophrenics who had not been chronically hospitalized. One patient from among the original 23 was mute during both interviews and one other patient required so much prodding to speak that she could only be scored on some of the variables. Therefore the number for the final results varied from 21 to 22, depending on the variable rated. The median age of the sample was 20 years.

Procedure

All patients were given a standardized 15-minute interview during their first (time period 1) and seventh (time period 2) weeks of hospitalization by an experienced psychiatrist. To allow systematic evaluation of the verbal responses, all patients were given the same set of instructions, as follows:

> We're interested in how people who come to the ward feel about certain things and how they express themselves about various matters. We're interested in talking to you about it now, and then once again before you leave. So we'd like to spend about 15 minutes with you now, and once again before you leave the hospital, and ask you a few questions. We routinely tape record this so that I'm not sitting here busily jotting down notes while we're talking. We'd like you to talk for about seven minutes about anything you like other than mental health or the events leading up to your hospitalization—we'll talk about that later. So talk about anything—it could be about things at home with your family, or work, or school, or books, or things you like to do or see. . .anything.

The seven-minute monologue by the patient on a nonmental-health topic was followed by a seven-minute monologue by the patient on a mental health topic, using the following instructions: "Now we'd like you to speak for about seven minutes about the events leading up to your hospitalization."

All patients were directed to speak for seven minutes on each topic, with half of the patients being assigned the mental health question first. After the introduction, the interviewer only spoke when he found it necessary to encourage the patient to continue talking, and his comments were limited to that goal (e.g., "Could you please go on," or "Could you say more," etc.). All interviews were taped, transcribed afterward, and then rated inde-

pendently by two experienced clinicians on 13 variables. These 13 variables, which were rated on five-point scales, were designed to assess changes over time in the significance of recent life events for the patients, changes in their focus of attention, and changes in their organizational ability. Three of these 13 variables were later eliminated due to difficulty in obtaining satisfactory reliability. Satisfactory interrater reliability was obtained on the other ten variables, and these variables are listed in tables 1, 2, and 3.

RESULTS

The Schizophrenic Experience

Bowers (6) and others have written in a more global fashion about the course of an acute schizophrenic episode; among other things they emphasized the sense of heightened awareness these patients experience early in the course of their psychosis. As part of a larger ongoing research project on schizophrenia (7–10), we have begun to document in a more formal and systematic way the ongoing course of the psychotic episode by studying the patients' own recorded verbalizations.

Three general trends were noted in the material and examined in detail: 1) the changing significance of recent life events for the patient, i.e., how patients describe their psychosis initially and how they come to view it six to eight weeks later; particular emphasis was placed on how intensely involved and overinvolved the patients were in their psychosis, and how they came to make sense of their psychosis; 2) the changing focus of attention from past to future: over this same time period, although much of the original content remains, there is a change in the way it is viewed, and considerable new content emerges that is concerned less exclusively with the self and that focuses on interpersonal and future concerns; and 3) an increased ability to organize communication: there is a growing capacity for following directions and for more logical, coherent, organized verbalizations.

Since this investigation is based on a sample of 23 acutely ill schizophrenics studied over two time periods during the course of their illness, five patients are quoted rather extensively. Although the focus is on verbalizations from these five acute schizophrenics, the data from the remaining patients were also analyzed and are presented to provide detailed information on the generality of each trend reported.

The Changing Significance of Recent Life Events

When the patients described the events leading up to their hospitalization, 82 percent (18 of the 22) became lost in an overwhelming flood of details. The early excerpts consisted of *vivid, detailed* descriptions, *lists of events*, and near-catalogues. The patients at this time were caught up and involved in their experience and took little distance from it. They were unable to sort out details; there was no hierarchy of importance. After partial recovery (at time period 2), in contrast, 15 of the patients (83 percent) who were overinvolved at time period 1 had taken considerable distance from their experience and talked of it in a more conventional, socially acceptable, condensed form.

In the following, a young graduate student, when asked what events led up to his hospitalization, talks at considerable length and with great intensity of a series of problems and decisions that gradually overwhelmed him. He constantly gets drawn up into his delusional system of a model that will predict the future, including his own death:

> Well, I was working on. . .I had tried to predict things, and I. . .I do a lot of simulation work. . .with animal populations. . . .And I was trying to. . .get a model based on genetics that would predict what harvest schemes we could use, and, would harvest. . .for harvesting ducks. . .based on the genes. . .the genotypes that they had. So I got working on that. And I'd worked on it all week until Friday. . .Friday night, till 11 o'clock, when I went to a party, and I had a few beers. Then. . .then I started working on this thing the next day some more, and I just went wild with it and started getting away from ducks and into people. And I planned to. . .I put. . .I kept putting myself. . . they kept saying that. . . that I'd reached a point of instability in which. . .I couldn't. . .there weren't. . .I couldn't figure out a way I could get beyond this point of instability. Uh, I. . .I would put myself into the model. . .trying to predict whether I should be going on. . .to a Ph.D. next year. . .at the University of _____. . .I kept wondering whether I should get married. . .whether I should settle down in _____. . .just what I should do. I got. . .I got so many alternatives. . .uh. . .decisions that I just went all out with it. And, uh, then I figured that. . .well, I predicted that I was going to die. (Sentence omitted.) Uh, so that I thought that this model was right in saying that the world was coming to an end, and it was my feeling that the world was coming to an end. But the model said I shouldn't tell anybody about the model, that that would just lead to chaos.

Six weeks later he has taken a good deal of distance from his delusions. When he does talk about them, he uses borrowed *clinical terminology* and psychiatric jargon, and he is much more general, much less concrete, than previously. The content is to some extent similar, but he makes the same content much less immediate for himself; actual details are less significant and important:

> Uh. . .well, I'd been working on a paper. . .uh, working pretty hard on it. . . and I got so involved in it that I lost a sense of. . .uh. . .what was real and what wasn't real. . .and I started having all kinds of racing thoughts and hallucinations, seeing things and hearing things. . .and. . .uh. . .(five-second pause) . . .it's like a bad experience, it seems that your mind seems to put it out of your mind . . . your mind seems to put it away where you can't get at it . . . because it's hard for me now to think of. . .I can think of some things. But it's hard for me to draw on how my emotions were at that time.

Later on in the interview he himself explains the distancing maneuvers he is going through. He is painfully aware of the *implications of the material*, i.e., that he was recently psychotic, is just recovering from that psychosis, and is not certain whether he might not be overwhelmed

TABLE 1
Changing Significance of Recent Life Events for Patients

Variable	More Pathology at Time Period 2	Same Level of Pathology at Time Period 2	Less Pathology at Time Period 2	Significant Difference
Overdetailed verbalizations	3	4	15	$p<.01$
Vividness of verbalizations	3	2	17	$p<.001$
Delusional verbalizations	0	8	14	$p<.001$
Overall significance of events	1	3	18	$p<.001$

and psychotic again. It is clear that the material has not been repressed or forgotten but that he is attempting to *reinterpret* it. He himself would like the entire experience to be much less vivid:

Uh...I have trouble getting distance from my problems, I can't seem to get them out of my head. I find that even now it's really hard for me to handle problems. I really have to really concentrate and say stop, you know, back off. That's one thing I picked up here (in the hospital). Uh...it's kind of a syndrome I get into—I get thinking about things and I don't get to sleep at night—I wake up early in the morning...I get completely run down...I just hope that I learned how to back off.

Another young college student, also schizophrenic, when asked shortly after admission what had led up to his hospitalization, replies in great detail, aimlessly listing a number of elements with no imposed organization and with no conviction. For instance, when he describes the theft of a car, he is *caught up and involved* in his story; he supplies a flood of details surrounding the episode, which is especially interesting in its autistic quality, in his blending internal belief with external reality:

For one—uh, I accidentally stole an automobile 'cause I was so high on drugs, and, uh, not the night before, but it was just an accumulation of all the days put together that, you know, your brain can only take so much. So, I had...I was looking for something...I always did want a fast car in my life...it's uh...since I was born that's all I thought about is having my own car...registered in my own name...and have the title in my own name...etc. So, after buying a few cars, I found out that I really wanted a fast car. So what I did was I saw this car...which happened to be...I thought it was Jimi Hendrix's car, you know, he's dead, because he had driven a Mustang while he stayed on Maui—and he had a pretty powerful engine in it—and I looked at this car and I looked around and I couldn't see any people when I first approached this car, while being high on drugs, everything looked kind of...sort of abandoned, and I looked at the car and it was in perfect shape, the keys were in it, it looked like it was just ready for me to go drive off. I got into the thing and I drove off! Thinking that it was Jimi Hendrix's ex-car, you know, I thought the machine was his—it could have been very well his car because it was such a popular car and I had a lot of time in it...I had a lot of good fun in it...I had so much good fun that I ended up with about ten policemen on my back—after driving the car. (Laughter.)

In the above quotation he almost relives the experience, as he builds up false hypotheses from chance detail. When asked the same question toward the end of his hospitalization, he begins his answer by stating that he was upset over the accidental death of an old girl friend, a relatively unlikely reason, but one that is somewhat more conventional and acceptable to him, since it provides a *causal*, much more *socially acceptable, integrated* explanation for his behavior. His mention of the episode with the car is briefer, shows *increased distance*, and has been pared of his delusional belief that it belonged to a famous, deceased pop singer. The *heightened attention* to details is gone; individual details are much less significant and important:

And, uh, before I knew it, uh, I had gotten an automobile...I had stolen an automobile with all intentions of returning it...but, uh, I found out that I was so screwed up on drugs that...I would *never* do anything like that—steal a car! But at the time it didn't come to me—I was too stoned to realize it—and before I knew it there I am on the road racing a Mustang up and down the street and then having ten policemen come after me.

Table 1 presents a more detailed summary of the results on the changing significance of recent life events for the patients during partial recovery. The change scores on each of the four variables were found to be significant, using the individual change scores and calculating t tests of the change scores. Most of the patients who did not change in the direction of less psychopathology at time period 2 were among the few patients who did not show difficulty in this area at time period 1.

The Changing Focus of Attention

During the height of the acute psychosis, 18 of the 22 patients (82 percent) were self-immersed and extremely preoccupied with themselves. Fifteen of the 22 (68 percent) were preoccupied with the past and with the aggravating events or people they saw as leading to their hospitalization. As a group these patients, who were initially so self-centered and past-oriented at time period 1, were much more future-oriented at time period 2 ($p < .001$). Table 2 presents the detailed data on the change scores at time period 2 for each of the four variables in this area, again using t tests of the change scores.

Note the egocentricity demonstrated in the following excerpt from a young housewife who had had recurrent psychotic episodes triggered by marital difficulties. When she is asked, shortly after admission, to talk about any-

TABLE 2
Patients' Changing Focus of Attention

Variable	Increased at Time Period 2	Same at Time Period 2	Decreased at Time Period 2	Significant Difference
Concern with past	2	4	16	$p<.001$
Concern with present	7	8	7	n.s.
Concern with future	17	5	0	$p<.001$
Self-immersion	2	3	17	$p<.001$

thing she chooses, she can talk only about her husband and herself:

Wow. . .uh, right now I see that, uh. . .my husband does want a divorce. Now, he doesn't want to be married now. And, uh, he still considers me as a baby, which I'm not. And, uh, I got the feeling last night that he has someone else to go to besides me, and I know he's concerned, he's very concerned about my being here. . .he proved that in family meeting, he's very concerned. And, uh, I was glad that he was. And, uh, just to him. . .going to a psychiatrist is hogwash. . .a lot of baloney. . .'cause he has a brother who believes psychiatrists are just crazy.

In striking contrast to this, at the time of discharge, when asked to speak about anything she chooses, she no longer talks broodingly about her husband, but about her children, her brothers, her medication, and concerns she has in the present and for the *future*. There is a marked *change in her preoccupation*:

O.K. I enjoy being with my children and we really had a good weekend—we took them to the carnival, I bought them books, and I bought them . . . uh . . . they got new dresses . . . Christine has a new dress for school . . . getting their clothes organized, and . . . uh . . . (interruption) . . . getting their clothes organized and . . . uh . . . I enjoy being with the children most of all. That's my main . . . idea . . . uh . . . just being with them . . . it makes me happy . . . it makes them happy. And . . . uh . . . getting support from my brothers that I never got before . . . which I'm getting now. And . . . uh . . . I'm worried about . . . about taking medication . . . you know, uh . . . maybe for the rest of my life.

Fittingly, at the close of the interview at time period 1, she is still talking about her husband, about the *past*:

We've known each other since I was 16 . . . 18 . . . I was 16 . . . he was 18. We never split up, when we were going steady. We fought like cats and dogs, but never split up. But, maybe for two weeks—that's going steady. And when we were married, the same thing . . . well, he had his problems, too. He lost his mother . . . his father two days after we got married . . . he lost his mother two years ago. And this has, you know, built up.

In contrast again, at the close of the interview at time period 2, she is working at putting the self-destructive relationship behind her and is concerned about her behavior in the *future:*

And I think now I'll be better off without him, 'cause every time I see him I get upset. And I don't want to feel that way . . . the less I see of him, I mean, the better off I am.

Although we had originally hypothesized that at time period 2 the patients would also become less present-oriented as they entered into partial recovery, the data in table 2 did not support this formulation, despite the significant results in the other areas studied.

Increased Ability to Organize Communications

As improvement occurred, the tendency for the patient to organize his thoughts in a more logically coherent fashion became increasingly apparent. This was evident throughout the series. An increasing organizational ability was apparent, an increasing ability *to follow the task* and keep to a set. Patients showed more capacity to structure their thoughts along time dimensions, and there was a decrease in abrupt shifts in tense. Preliminary analysis shows that certain types of looseness of associations are moderately frequent during the acute stage, but tend to diminish as the patient begins to recover. Clear blocking was not frequent for these *acute* schizophrenics, even at the height of the acute psychotic break.

Initially, many of the patients showed considerable disorganization. Eight of the patients were unable to follow directions precisely, in terms of talking about the topics assigned during the instructions by the interviewer. In addition, it was difficult to follow 16 of the 22 patients' train of thought during at least part of the interview. By time period 2, there was marked improvement, and this improvement is summarized in table 3. For example, at time period 1 a young schizophrenic man talked of what had happened to him prior to hospitalization. Some of his usage is idiosyncratic. There are abrupt time shifts. He appears confused at times. There are sudden shifts in thought and a lack of logical connection of ideas. It is difficult to follow his train of thought:

O.K. Briefly, there's a rumor that got me here. Here I was—my mind finally got together after being introverted for nine months. I was in jail. I got out a 25-day sentence for penicillin without a prescription, phenobarbital—I had two phenobarbitals—I didn't even know what they were. Asthma, Benadryl, Bayer aspirin—so they booked me and I got 30 days in Erie County Penitentiary and when I first went in . . . first went in and I dug every minute of it . . . like I walked in with the attitude—here's my new home—far out—I never lived in a house this big, you know. So they said would I check my pack in? Check it in, went in. I wrote on the I beam facing in—you're not

allowed to write on it—I wrote "Home is where you're at"—which I believe in strongly. And O.K. A couple of weeks ago my head finally snapped together again to where it used to be 'cause I'd gone to jail like I was an extrovert—I'd just become extrovert after being an introvert all my life. And I was digging the extrovert. And I went to jail and after two weeks I couldn't handle it—and I went pppfffttt!!!—and I was 16 years old mentally and physically when I walked out of the place. I had to learn how to talk to girls again without being up-tight—the whole adolescence trip—and here I was a day later in college. And I'd taken—in the fall—or in the spring—a leave of absence—I had enough homework for nine months and I had to hit the books so I had no time to relax, I was still up-tight from jail. (Note: marked confusion and abrupt time shift.) And the end of the first semester I was 17 years old and all my friends—I couldn't relate to anybody—I mean how could a 16-year-old relate to a college scene? It was very hard and I was so severely alienated—and I was in suicide alley all the way—like I could just sit down and cry for hours each day 'cause I couldn't get my head back to where it used to be. I was so boned out. I was paranoid of everybody, I was scared to death of people, I was in jail and I had some real nasty experiences—I didn't get raped, but my head got fucked over just the same.

Six weeks later, he is much more organized and not so flooded with details. This improvement is much more impressive in view of the fact that the day prior to the second taping he had been acutely agitated:

(Chuckle)... (clears throat)—(pause) Well, I'll start way back in jail—I had an experience where I ended up in jail for 25 days and I walked out I was mentally like a 15-year-old... I was embarrassed at girls... I was introverted... I was, you know, really depressed... and wanted to commit suicide. Like I'd try to do homework and I'd sit there and just cry 'cause I couldn't do it. Total alienation and frustration which led to my mother bringing me home in the middle of the week to calm down which helped a great deal and things looked bad and the future looked bad—and I was scared to death of what was happening to me.

Even more striking are these final excerpts from a young schizophrenic girl. There is great pressure of speech, almost no logical connection between sentences, and usage that is idiosyncratic. The topic switches at breakneck speed, and she is confused throughout.

Well... I do like to cook sometimes.... It seems like I'm not cooperative with anybody anymore. It seems like everybody runs on one track and one's on another; it seems to me like everybody's running around. I think I'm making myself this nervous because I eat too much. I don't know how much to eat or anything, and that's just it—I don't know what I want to do all day long and I have to ask people and then one girl—well, they keep switching back and forth—like one will be on Monitor and one will be a buddy or something—I'm still confused about that—and... going out for a walk yesterday—I wanted to get out—but it was kind of cold outside, and I... um... a lot of times I worry about my parents—if they've gotten home or not or if they've been tied up somewhere. And... I don't feel like I'm crying to people—the way I act I feel like I'm kind of bold, and hurting them. And, uh... that's just it—I don't know what I want to do. I'm all confused. And, uh... I'll talk to one person about one thing—and I'll talk to another person about something else—and maybe I'll get them all confused that way. And, uh... like I have no sense of direction—somebody's got to lead me by the hand.

A month and a half later, though still showing some signs of psychosis, she can at least hold to one topic for a period of time. She does not switch subjects rapidly, and the passage is coherent. As noted above, she too is much more future-oriented:

I don't know about school yet, and Dr. _____ was ordering a tutor—I don't know if she's going to come or not. It would take up some of my time here. And, uh, I'm not ready to go back to school, I don't think. If I did I'd just take up one or two subjects. (Sentence omitted.) I'm getting a little used to this place now. It's not... it's not as scary as it used to be... when I first came in I was really tense—now I feel like I'm more relaxed. And I think I'm getting used to it now. Tomorrow... well, I'll probably go out for a buddy walk—'cause I got on the buddy system today... I feel very good about that. And I'm anxious to get home too. I want to see my friends at church, and, you know, different people like that. 'Cause I miss them a lot. And, uh... I don't know... I just feel very happy today. Probably 'cause I got on the buddy system. It's... I'm just happy.

A more quantitative analysis of the interviews is being conducted now. At this point, however, it is valuable to note the striking changes in the quality of the patients' verbalizations as the psychotic picture becomes less flagrant. For instance, preliminary analysis indicated that looseness of associations was significantly decreased by time period 2. It is also worthwhile to point out that striking examples of blocking, such as this one from time period 1—"I thought I could settle down to a life with my girl friend—I feel like, uh,—I, uh (pause)—I urinate a lot, especially when I'm nervous..."—are never prominent even at time period 1 and are almost entirely absent by time period 2.

TABLE 3
Ability of Patients to Organize Their Communications

Variable	More Pathology at Time Period 2	Same Level of Pathology at Time Period 2	Less Pathology at Time Period 2	Significant Difference
Unable to follow directions	0	12	9	$p<.01$
Unable to follow train of thought	2	3	16	$p<.001$

SUMMARY AND IMPLICATIONS

In conclusion, a number of clear trends emerged from the patients' verbal material. During the height of his psychosis, the schizophrenic becomes lost in an overwhelming flood of details. The vivid, detailed descriptions formally document the patient's loss of distance and his intense overinvolvement in his experience (11) and indicate a probable heightened awareness.

After partial remission, some change in content is consistently documented. In our data many of the incidents described at excessive length at time period 1 are referred to at time period 2, but references to them are briefer, more socially conventional, detached, and concise; specific details and events are remarkably less significant and prominent. This material, then, would support theories that in acute psychosis there is an impaired ability to respond selectively to the external world and would also indicate that this ability to respond selectively and to take distance are rapidly regained as the acute psychosis subsides. After remission there is also a significant content shift to future concerns. This change in time orientation may be part of the natural course of the illness, or psychotherapy and the treatment values of the milieu may orient patients to think about their future as they emerge from their psychosis. Moreover, there is a decrease in preoccupation with self and there is a renewed interest in interpersonal relationships and responsibilities.

Finally, in regard to the patterns of speech and the quality of thought, our data would support formulations about the presence of some looseness of associations during the acute schizophrenic episode. However, preliminary analysis shows that the looseness tends to diminish as the patient begins to recover. Moreover, our preliminary data would indicate that blocking and neologisms, long considered essential phenomena of schizophrenic thinking, are in reality not frequent even at the height of the *acute* schizophrenic episode. It is also of marked interest that in our sample there does not appear to be greater disorganization in schizophrenic speech when the patient is faced with what could be considered a stressful, rather than a nonstressful, topic to discuss.

The data suggest that in an active treatment setting at least some of the flagrant psychotic features present in the acute schizophrenic patient begin to diminish (or disappear) during a relatively short recovery period.

DISCUSSION

ALFRED B. LEWIS, JR., M.D. (New York, N.Y.)—In studying changes in the thought content of acute schizophrenics, the authors have come up with three general conclusions. Partial recovery from the acute episode is associated with: 1) greater "distance" from recent life events, 2) a change in the focus of attention from recent past to future and from the self to other people, and 3) improved organization of communication.

This paper raises several interesting issues related to an understanding of schizophrenia, but I will confine my comments to two points: 1) the concept of ego-boundary breakdown in schizophrenia and 2) the implications of these findings for treatment.

The patients described by the authors can be viewed as suffering severe ego-boundary pathology. These patients cannot keep separate what originates from within and what originates from the environment. The result may be described in terms of "loss of distance," "overinvolvement," or, in extreme cases, a tendency to "fuse" with the environment and to lose the ability to delineate the self from its surroundings. The gradual reestablishment of "distance" from recent life events during the recovery process may also be viewed as a reestablishment of the integrity of the ego boundary.

An interesting question is: What is the relationship of ego-boundary diffusion to the breakdown of repression that is alleged to occur in schizophrenic disorganization? Just as there is a theoretical boundary between the self and the outside, there is also a theoretical boundary between conscious awareness and the unconscious—a kind of "internal ego boundary." The permeability of this boundary permits an upsurge of impulse and fantasy from the unconscious that some clinicians regard as characteristic of schizophrenic thinking. Do both the external and internal ego boundaries break down in acute schizophrenia? Or does one or the other break down selectively? And if the latter, is the site of the boundary breakdown related to the acuteness of the process, the subtype of schizophrenia that develops, or the preexisting personality structure?

It is possible, for example, that acute undifferentiated schizophrenics, who suffer clinically from ego-boundary breakdown (the kind described by the authors), are in actuality suffering from an inability to screen relevant from irrelevant incoming information. The development of chronicity, and perhaps the differentiation into one of the subtypes of schizophrenia, may represent an effort to cope with a sense of being overwhelmed by this information, either by selectively attending largely to internal stimuli such as might occur in catatonic withdrawl or by selectively attending to a narrowed area of external stimuli, such as might occur in the formation of paranoid delusions.

For example, patients with premorbid hysterical personalities, who tend to be very suggestible, may be more predisposed to external ego-boundary breakdown, while those with premorbid obsessional personalities, who have relatively weak repression to begin with, may be more predisposed to internal boundary breakdown.

My second point concerns the implications of this work for the treatment of acute schizophrenia. If the process of recovery seems to be characterized by the development of increasing distance from threatening life events and experiences, and by the focusing of greater attention on other people and on the future, then the acute schizophrenic should probably be discouraged from talking about the recent past with which he is so preoccupied. Psychotherapy sessions and interaction with staff members should probably be handled in a structured way, so as to minimize the loosening of the thought processes. Persistent efforts should be made to focus the patient's attention on the future, and on other people in the present, in order to encourage the development of distance.

These may seem like relatively simple-minded ideas, but in many active treatment units the patient is exposed from the beginning of his hospitalization to the same kind of stimuli that he has difficulty distancing himself from. For example, he may be permitted visits from family members and friends who are intimately involved in his recent life experiences. He may be subject to detailed questioning by his therapist about the events of his present illness. He may be encouraged to talk about it by staff members or other patients in group therapy or community meetings. Such procedures might tend to slow down the distancing that seems to be such an important part of the recovery process in acute schizophrenia.

As a further illustration of this point, the next time I see an acute undifferentiated schizophrenic on my inpatient unit, I am going to advise the resident and the nurses to talk to him about anything *but* the events of his present illness—remote past, future, other people, even the weather—in an effort to accelerate this process of distancing that seems to be associated with recovery.

Alcoholics' Patterns of Controlled Drinking

BY EDWARD GOTTHEIL, M.D., PH.D., ARTHUR I. ALTERMAN, PH.D., THOMAS E. SKOLODA, M.A., AND BRENDAN F. MURPHY, M.S.W.

Groups of seven to ten volunteer alcoholic patients were studied and treated on a closed ward where alcohol was available. Of 66 patients who completed the program, 44 percent did not drink at any time, 33 percent drank throughout the drinking phase of the program, and 23 percent began drinking and then stopped. The results of this study question the assumption that drinking by alcoholics necessarily results in irresistible craving, more drinking, and loss of control. The authors point out the need for research into the circumstances and maneuvers that influence resistance to drinking.

A NUMBER OF THEORIES about why people drink excessively were recently grouped into various lay and professional models of alcoholism by Siegler and his coworkers (1). In what they described as a "new medical model," alcoholism was defined as a progressive and often fatal disease that was possibly hereditary and that occurred in individuals with a particular body chemistry. The hypothesis of an organic predisposition to alcoholism is not uncommon (2–7) and is compatible with the conception that an alcoholic can never drink in a controlled manner. From this point of view, the first drink a predisposed individual takes inevitably results in irresistible "craving," more drinking, and "loss of control." However, some recent findings are bringing these concepts into question.

Merry (8) and Paredes and associates (9) found that a single drink did not necessarily trigger physiological craving, loss of control, or undesirable behavior in their patients. Several studies have indicated that some alcoholics could return to moderate and controlled drinking (10–13). Mello and Mendelson (14) reviewed the work on experimentally induced intoxication and concluded that alcoholic subjects demonstrated more control over their drinking behavior than was compatible with a concept of craving. For example, their subjects did not drink all of the alcohol available to them in spontaneous drinking situations. Periods of heavier drinking alternated with periods of lighter drinking and even brief periods of abstinence. Under operant conditions they earned less alcohol when the amount of work required for a given amount of alcohol was increased, even though it was still easily within their capacity to earn more. These last observations were generally corroborated by Nathan and associates (15). Cohen and her associates (16) found that by increasing the amount of monetary reinforcement they could purchase single days of abstinence from each of four patients even when they scheduled a delay in payment or administered a priming dose of alcohol.

In our Fixed Interval Drinking Decisions (FIDD) program (17–19), alcoholic patients were studied and treated on a closed ward; alcohol was available and they could elect to drink or not drink at predetermined intervals. Without programmed rewards or punishments for drinking or abstaining, eight of 25 patients were found to drink throughout the four drinking weeks of the program, eight began drinking but stopped, and nine never drank at all in the presence of available alcohol and other drinking patients. Nevertheless, many workers in the field believe that alcoholism is characterized by craving and loss of control. Marconi and his co-workers (20, 21), on the basis of their neurophysiopathogenic theory and experimental results, described the following three forms of physical dependence in which patients experienced a state of distress and an overpowering desire to consume more ethanol: 1) a primary physical dependence without previous ingestion of ethanol, 2) an inability to stop after ingesting a small quantity of alcohol, and 3) an inability to abstain after continuous drinking.

This paper includes a description of the drinking patterns of 66 patients who have now completed the FIDD program. For those patients who stopped drinking during the program, measures of self-esteem, sleep disturbance, socialization, and discomfort obtained before and after they stopped drinking were compared. In addition, the test scores of these "stoppers" were compared with their drinking behavior after a six-month follow-up period.

METHOD

The development, rationale, criteria for patient selec-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are all with Coatesville VA Hospital, Coatesville, Pa., where Dr. Gottheil is Consultant, Dr. Alterman and Mr. Skoloda are Research Psychologists, and Mr. Murphy is Research Social Worker; Drs. Gottheil and Alterman are also with Jefferson Medical College, Philadelphia, Pa. 19107, where Dr. Gottheil is Professor of Psychiatry and Dr. Alterman is Instructor in Psychiatry (Psychology).

The authors wish to thank Otto Schaefer, M.D., Director, and Floyd S. Cornelison, Jr., M.D., Chairman of the Dean's Committee, Coatesville VA Hospital, for their administrative support and guidance; Harold D. Crawford, for his assistance in collecting the data; and the many other members of the hospital staff and research committee, for their cooperation and contributions to the day-to-day operation of the program.

tion, therapeutic program, and some research findings of the Fixed Interval Drinking Decisions program have been described in earlier papers (17–19). Briefly, groups of seven to ten volunteer male alcoholic patients between the ages of 25 and 55, without psychosis or serious medical or neurological disease, were studied and treated on a closed ward in the presence of alcohol.

The program began with a *predrinking week* during which alcohol was not available. A varied multidisciplinary treatment program was initiated and baseline studies were performed. This was followed by a four-week *FIDD phase* in which the patients could elect to drink zero, one, or two ounces of ethyl alcohol, straight or with water, each hour on the hour from 9:00 a.m. to 9:00 p.m., Monday through Friday. If the patient decided that he wanted a drink, he came to the nursing station at the appointed time, received his alcohol, and drank it there. The time and amount were recorded by the nursing personnel. This schedule provided 13 decision points daily and a maximum intake of 26 ounces. The staff attempted to maintain a neutral—neither encouraging nor discouraging—attitude toward drinking while helping the patient think about his problems and drinking decisions. Psychotropic medication was not prescribed. A *post-drinking week* completed the program cycle. Alcohol was not available, the initial baseline studies were repeated, and discharge, transfer, or other posttreatment plans were developed and implemented.

Test Variables

Situational discomfort. A 17-item adjective checklist (19) was administered three times each day throughout the six weeks of the program. The patients indicated the extent to which they felt nervous, gloomy, angry, fearful, etc., on five-point scales. Average daily and weekly scores were calculated.

Sleep disturbance. Daily responses were obtained to a six-item sleep inventory. The inventory included such questions as "Did you have a restful night's sleep?" and "How many times did you wake up last night?"

Self-esteem. Once a week the patients were asked to rate themselves according to whether they were more like one or the other of 16 pairs of contrasting adjectives (22, 23). The ratings were made on seven-point bipolar scales, with a higher total score indicating a more favorable self-description.

Socialization. Observations of socialization behavior during waking hours were made and recorded by nursing attendants at half-hour intervals. A withdrawal score was obtained by counting the number of times a day that an individual was checked as being alone in his room and a socialization score by counting the number of times an individual was checked as actively engaged in socializing (group discussion, playing pool, etc.).

Follow-up questionnaire. Six months after leaving the program, patients were sent a questionnaire that included such items as whether and when they took their first drink, whether and when they first became intoxicated, and the number of days on which they drank and became intoxicated during the past month. They were also asked to compare how they felt and how much they were drinking before and after the program and the extent to which they had been helped. If no response was received, telephone contact was attempted. Patients whose responses to the questionnaire items indicated that they were: 1) feeling better, 2) drinking less, 3) had been helped, and 4) had not been intoxicated more than once during the past 30 days were considered to be improved.

RESULTS

At present, 66 of 76 patients have completed the FIDD program. Six patients were found to have disqualifying illnesses that had not been detected or established during the initial screening examinations. One patient became hostile, assaulted another patient, and was transferred out of the program. Three patients withdrew from the program. Of the remaining 66 patients, 29 (44 percent) did not drink at all, 22 (33 percent) drank throughout the drinking phase of the program, and 15 (23 percent) began drinking and then stopped.

"Stoppers" were defined as individuals who had had some alcohol at some time during the first three drinking weeks but had not taken a single drink during the fourth drinking week of the program. They included 12 white and three black patients, with a mean age of 40.9 years and a mean educational level of 10.1 years. Only three of the 15 were married and living with their wives. They described themselves as having been drinking heavily for an average of 13.0 years. Blackouts had been experienced by 12 of the patients, "the shakes" by 11, delirium tremens by four, and convulsions by three; nine had been previously hospitalized for alcoholism. During the past year, ten had missed three or more months of work. The total amount of alcohol they consumed during the program, the percentage of possible drinking days on which they

drank, and the average amount ingested on the drinking days are indicated in table 1. The number of possible drinking days varied from group to group since holidays were treated as weekend days and alcohol was not available.

Inspection of table 1 reveals a broad range of drinking patterns. For example, K. drank 22 oz. on one day and did not drink again. M., N., and O. drank small amounts occasionally. Patients C. and G. drank about 11 oz. a day with little variation until they stopped, while I. began drinking heavily and gradually tapered off over a two-week period. F. drank heavily for five days and A. for 13 days before abruptly stopping.

The continuing drinkers also demonstrated a wider variety of drinking patterns than would be expected from a "loss of control" hypothesis (table 2). Thus, patient U.U. drank moderately on 65 percent of the possible drinking days and never exceeded 8 oz. a day. Patient T.T. also drank moderately but was more consistent and drank on 95 percent of the drinking days. Both P.P. and Q.Q. drank about 10 oz. a day, but P.P. drank on every possible drinking day with little daily variation, while Q.Q. drank as many as 20 and as few as 3 oz. a day and abstained entirely on several days. Even a heavy drinker, such as J.J., varied his daily intake from 6 to 26 oz. Patient O.O. drank heavily on about two-thirds of the drinking days and not at all on the other third. His abstinent days were interspersed among his drinking days in no set pattern. Moreover, the abrupt termination of the availability of alcohol on nights, weekends, and holidays was accepted by the patients without apparent difficulty.

The "stoppers" provided us with an opportunity to obtain repeated observations when they were drinking (first drinking week) and also after they had stopped and were resisting further alcohol while on a closed ward in the presence of other drinking patients (fourth drinking week). Clinically, these patients appeared to tolerate their voluntary termination of drinking rather well and they did not verbalize any craving for alcohol. Their scores on the measure of discomfort (table 3) did not increase but tended to decrease somewhat from the first to the fourth drinking week of the program. Their self-esteem increased and sleep disturbances decreased significantly, while there were no significant changes in withdrawal or socialization.

According to our criteria, seven of the "stoppers" were categorized as improved at the six-month follow-up. Six patients who did not meet the criteria and two who did not return completed follow-up questionnaires were included in the unimproved category. The improved group did not differ from the unimproved group with respect to educational level, marital status, or occupational stability. The three black patients were all in the improved group. The unimproved group, on the average, was about nine years older (45.3 compared to 36.0 years; $p<.05$, by one-tailed t test) and had been drinking heavily about nine years longer (16.8 compared to 7.1 years; $p<.05$, by one-tailed t test) than the improved group. However, there was no difference between the groups in "severity" of alcoholism as indicated by scores on the MacAndrew Alcoholism Scale (24) or the Drinking Behavior Inventory (25).

The mean scores on sleep disturbance, discomfort, self-esteem, withdrawal, and socialization obtained by the improved and unimproved groups during their first and fourth drinking weeks on the FIDD program are indicated in table 4. In comparison with the "stoppers" who were improved at six-month follow-up, those who were not doing as well had slept more poorly, were more uncomfortable, had less self-esteem, and were more withdrawn while they were in the program.

DISCUSSION

The data are not consistent with the theoretical posi-

tion that drinking by the alcoholic necessarily results in irresistible craving, more drinking, and loss of control. Some of the patients did not drink at all, some drank heavily and then stopped, and some were able to drink moderately and also stop. Even among heavy drinkers, the alcohol intake varied from day to day, drinks could be resisted after large amounts had been ingested, and abstinent days alternated with drinking days.

The patients who stopped drinking appeared to tolerate this rather well and did not express any strong craving for alcohol. Moreover, while resisting further alcohol, they slept better than they had while drinking, their self-esteem increased, they tended to experience less discomfort, and there was no significant change in withdrawal or socialization.

It should be made explicit that these results, as well as those obtained in other studies of experimentally induced intoxication, were based on restricted samples of patients under sheltered, laboratory conditions. Therefore, the findings may have different implications for treatment applications than for research studies.

Although properly criticized by Merry (8) and Pattison (26, 27), the "loss of control" concept, coupled with the goal of complete abstinence, has been extremely useful as it has been applied by Alcoholics Anonymous. They have treated and are treating successfully more alcoholic patients than all other treatment agencies combined (28). Until the researcher is able to demonstrate some better practical techniques, the A.A. approach continues to merit our admiration and endorsement. Unfortunately, many alcoholic patients are unwilling to attend and many are not helped by Alcoholics Anonymous. The number of cases of alcoholism has increased rather than decreased over the years. Further studies are required, therefore, if we are to improve treatment techniques, achieve more understanding, and develop some avenues to prevention.

The patients exhibited varying degrees of control over their drinking behavior while they were on the FIDD program. There is no doubt, however, that there were many times in the past when they had lost control of their drinking and their other affairs. How and why, then, is a patient able to control his drinking at certain times, and what factors make him unable to resist alcohol at other times, under other circumstances? Since the degree and pattern of control varies from patient to patient and from time to time within the same patient, the question for further research is not whether there is loss of control over alcohol or not. Rather, there are many questions about the circumstances and maneuvers that promote more or less resistance to drinking.

Questions of the Month

For each of the incomplete statements below, *one* or *more* of the completions given is correct. Choose:

A if only *1, 2, and 3* are correct,
B if only *1 and 3* are correct,
C if only *2 and 4* are correct,
D if only *4* is correct,
E if all are correct.

Question 1

Fixation may occur as a result of
(1) over-indulgence
(2) very early toilet training
(3) prolonged dependency gratification
(4) deprivation

Question 2

The Authority which approves residency training programs in the United States includes the
(1) American Medical Association
(2) American Psychiatric Association
(3) American Board of Psychiatry and Neurology, Inc.
(4) National Institute of Mental Health

(The Questions of the Month are from the Self-Assessment Program of APA. The answers are supplied on page 434 of this issue.)

Treatment of Fear of Flying

BY LESLIE SOLYOM, M.D., RICHARD SHUGAR, SHIRLEY BRYNTWICK, AND CAROL SOLYOM, M.A.

In a study of treatment efficacy for 40 patients with air travel phobia, three behavior therapy techniques—aversion relief, systematic desensitization, and habituation—proved equally effective in significantly reducing the phobia, while group psychotherapy was ineffective. However, at follow-up the difference between the two approaches was no longer significant. The authors suggest that the behavior therapy techniques achieved a more immediate result because they were more directly symptom-oriented. In addition, prior extensive flying experience tended to reduce the benefits from treatment.

AGRAS, SYLVESTER, AND OLIVEAU (1), in an epidemiological study of phobias in the greater Burlington, Vt., area, reported fear of flying as intense in ten percent of the population and as mild in 20 percent.

Conventional psychotherapy has been minimally effective in treating fear of flying in military pilots (2–4). More recently, Goorney (5), using systematic desensitization, was able to return five of six experienced aviators to full flying duties. In Aitken and associates' (6) series of 18 military pilots, however, similar treatment was effective in only one-third. For civilian air travelers, desensitization was effective in one case of fear of flying (7) but not in another (8), and drug-assisted desensitization was successful in treating two cases (9).

This paper is a part of an investigation into the effects of different behavior therapy techniques on phobic neurosis (10–12). Air travel phobia was treated with one of three behavior therapy techniques (systematic desensitization, aversion relief, or habituation) or with group psychotherapy, and outcomes of the therapies were compared.

METHOD

Subjects

The best homogeneous sample of 40 patients was selected from a pool of air travel phobics referred by psychiatrists, private individuals, and airline companies. The criterion for selection was an overwhelming and intractable fear of flying manifested in either avoidance or in inability to travel by plane without excessive anxiety.

The first 20 subjects were matched as closely as possible on: 1) age, 2) education, 3) flying phobia score, 4) single phobia (only air travel phobia) versus multiple phobias (e.g., also fear of heights, closed spaces, weather, or open places), 5) duration of flying phobia, and 6) IPAT Anxiety Scale score. They were then randomly assigned to one of the four treatment groups. The other 20 subjects, recruited later, were assigned to the treatment groups to maintain the matched-group design.

Assessments

All subjects were assessed before treatment and one month after termination of treatment by:

1. Psychometric tests—IPAT Anxiety Scale, Wolpe-Lang (13) Fear Survey Schedule (FSS), and Maudsley Personality Inventory (MPI).

2. Psychiatric assessment in a semi-structured interview using a questionnaire detailing psychiatric history, flight experiences, previous psychiatric treatments, and so forth.

3. A 25-item questionnaire on fear of flying. Fear was rated by: 1) a phobia scale from 0 to 4, with 0 corresponding to "no uneasiness" and 4 to "terrifying panic attack if avoidance impossible"; 2) seven items reflecting a fear-motivated attitude, e.g., "Before going on a plane it is wise to buy travel insurance," "Driving a car is safer than driving in a plane"; and 3) in terms of general coping behavior.

On completion of treatment, patients were first requested to take a 35-minute trial flight and then to make a more extensive trip. The latter constituted the pass-or-fail test.

To measure permanency of improvement, a ten-point questionnaire was administered to all subjects 50 weeks after the termination of group psychotherapy sessions.

Therapies

All behavior therapies were administered in the same laboratory, which had been outfitted with 16 standard airplane seats and remote controlled motion picture and finger electric shock facilities. During sessions, subjects sat in the front row of the airplane seats, facing a large screen. The therapist administered the treatment from behind a one-way mirror.

The program of therapy incorporated the individual patient's past flying experiences, or what he imagined they would be, and a common audiovisual presentation

Single	3	1	1	0
Married	7	9	8	9
Divorced	0	0	1	1
Education (years)	12.4	12.9	11.6	13.5

of a flight. The 15-minute film showed airplanes taking off and landing, passenger activities on board, and scenes inside airports.

Systematic desensitization. This treatment was carried out according to the description by Wolpe (7). In four one-hour treatment sessions, the anxiety hierarchy was presented in gradual steps to the relaxed subject. During the next four one-hour sessions, the relaxed patient was repeatedly presented with the flight film. Therapy sessions were conducted twice weekly for a total of eight hours within a one-month period.

Aversion relief. Each subject was asked to write and then record three to five accounts (in the first person, present tense) of past flying experiences, describing not only the anxiety-provoking cues, i.e., roaring of the engines and air turbulence, but also the autonomic, cognitive, and behavioral components of his anxiety responses. During eight 30-minute therapy sessions, the tapes were presented to the subject through loudspeakers. Lapses of silence averaging 20 seconds in duration interrupted the narrative at appropriate points (prior to anxiety stimuli and responses) and were followed by finger electric shock (intensity midway between threshold and pain tolerance). Cessation of electric shock, when the patient pressed a button, occurred simultaneously with resumption of the tape presentation. Thus a feeling of relief due to the cessation of electric shock coincided with the description of an anxiety stimulus or an anxiety response.

In the next eight 30-minute sessions, the flight film was presented to the subject. Relief from electric shock was paired with the fear-provoking cues of the experience. An initial continuous reinforcement schedule (electric shock after every pause) was gradually reduced with repeated presentations to a 20-percent partial reinforcement schedule.

The following is an example of a phobic narrative for aversion relief treatment:

When I am—20 seconds—electric shock, button pressed [feeling of relief], *fastened to the seat*—20 seconds—electric shock, button pressed [feeling of relief], *I feel trapped*—20 seconds—electric shock, button pressed [feeling of relief], *my heart is racing.*

An example of a programmed film follows:

Scene of stewardess walking down the aisle—20 seconds—electric shock, button pressed [feeling of relief], (sound) *Fasten your seat belts*—20 seconds—electric shock, button pressed [feeling of relief], *Bumpy weather ahead.*

Habituation. Subjects in this group followed the same procedure as the aversion relief subjects. Tape and film presentations were interrupted but there was no electric shock, and therefore no aversion relief was administered.

Group psychotherapy. Five two-hour group psychotherapy sessions were conducted at weekly intervals. During the sessions, patients discussed their air travel phobias, other neurotic difficulties in terms of their developmental history, rationalizations, and so forth. After the five therapy sessions the group met at the airport with an experienced pilot who thoroughly discussed the safety of air travel, the training of pilots, and so forth, and answered their many questions. One week later, a practice flight, piloted by the same pilot, was arranged for the group and their therapist. Total therapy time amounted to 12 hours plus the 15-minute practice flight.

RESULTS

The general characteristics of the four groups and the group means on the initial values are given in tables 1–3.

No significant differences were found between the groups. However, the male:female ratio is small and the number of unmarried subjects relatively high in the aversion relief group (table 1).

The systematic desensitization and group psychotherapy groups' scores on the IPAT Anxiety Scale repre-

TABLE 2
Group Means on Psychometric Tests (Initial Measures)

Variable	Aversion Relief		Desensitization		Habituation		Group Psychotherapy	
	Mean	Range	Mean	Range	Mean	Range	Mean	Range
IPAT Sten score	7.0	3–9	5.9	3–10	7.0	3–10	6.6	5–9
FSS total fear score	103.8	53–139	84.9	22–146	118.1	52–210	87.5	19–132
MPI neuroticism score	26.2	8–46	21.0	5–40	25.6	2–45	18.8	6–36
MPI extroversion score	25.1	2–41	25.1	17–34	24.1	12–35	28.5	16–44

sented normal values and were lower than those in the aversion relief and habituation groups, but the differences were not statistically significant (table 2). FSS total scores for all four groups roughly corresponded to scores of individuals suffering from a specific phobia (e.g., of an animal or of heights) and fell between the scores of normal controls and those of agoraphobic patients (14).

No statistically significant difference was found in an overall analysis of variance.

In table 3 the mean phobia score represents an intensity of fear corresponding to "strong fear, avoidance if at all possible" in the three behavior therapy groups and to a slightly lower intensity of fear between "definite fear, tendency to avoid" and "strong fear, avoidance if at all possible" in the group psychotherapy group.

Subjects with only air travel phobia slightly outnumbered those who had multiple phobias. Only the habituation group had an equal distribution of subjects with single and multiple phobias.

Duration of phobia was calculated somewhat arbitrarily for older individuals who claimed that they had always been fearful of flying. It was assumed that air travel phobia developed only when travel by plane had become a practical possibility—about 1950. Maximum duration of phobia was therefore set at 21 years. Age at onset of phobia did not differ between the groups.

Previous flying experiences, in terms of number of flights taken, was similar among the groups. Because patients' recall proved unreliable beyond a high number of flights (discrepancies were found between different sources of data), six or more flights were arbitrarily counted as six. Only three subjects, two in the habituation group and one in group psychotherapy, had never flown.

For purposes of this report, data on outcome of treatment have been restricted to those measures directly related to air travel phobia. Did the subject take a plane? What is his phobia score? Has his attitude about flying changed?

Data are tabulated only for the individual and combined behavior therapy groups. In the group psychotherapy group, only one subject, who had never flown before, passed the test flight. The group's mean phobia score decreased from 2.8 to 2.5—a nonsignificant change. Changes on other variables were also insignificant.

TABLE 3
Pretreatment Measures of Phobia

Variable	Aversion Relief	Desensitization	Habituation	Group Psychotherapy
Mean phobia score	3.1	3.0	3.4	2.8
Ratio of single to multiple phobias	6:4	6:4	5:5	7:3
Agoraphobia	3	1	3	1
Mean duration of phobia (years)	13.6	11.6	10.2	10.2
Mean age at onset (years)	27.4	28.2	27.9	28.0
Mean number of flights	5.3	5.2	3.3	4.3

Results in the behavior therapy groups are given in table 4. Each group demonstrated a significant improvement in mean phobia score ($p < .01$). Differences between the groups are nonsignificant. The most important test was the flight test since it measures observable behavior. Seven or eight subjects in each of the aversion relief, systematic desensitization, and habituation groups passed the test flight—for an overall rate of 73 percent. The mean phobia score decreased by 1.7 units, with 15 subjects (50 percent) reporting a drop of two or more units. The magnitude of change in scores on the FSS airplane subscale was similar, but the shift in attitude was negligible. Results of the flight test were significantly related to other measures of outcome—phobia score ($\chi^2 = 20.5$, df=4, $p < .001$) and FSS airplane subscale score ($\chi^2 = 16.72$, df=4, $p < .01$).

Of the totally phobic group, i.e., subjects who could not fly at the beginning of treatment, 78 percent passed the test flight and changes in phobia score were similar to those of the total group. Slightly more individuals with multiple phobias (77 percent) passed the test flight than individuals with a single phobia (71 percent).

Group responses to a follow-up questionnaire are presented in table 5. Data were collected from 80 percent

Mean	8.0	5.4	1.8	1.7
Range	2–12	2–15	2–4	2–4

of the subjects. Of the remaining eight, two had left the province and have not yet replied; two reported that they had become pregnant and had given up all intent to fly at this time; and four subjects could not be located.

One subject in the aversion relief group suffered a temporary and slight setback but was later able to continue flying without fear. All other patients maintained their improvement. To our great surprise, five (50 percent) of the group psychotherapy subjects also took flights with much reduced or no anxiety. Not unexpectedly, however, anticipatory anxiety still continues to plague even some of the subjects who no longer experience anxiety during flight. A more extensive follow-up inquiry using the same assessments as before is currently under way.

Upon comparing those subjects who had flown less than six times before treatment with those who had flown more than six times, a nonsignificant but perhaps important result emerges. In the former group 85 percent passed the test flight, while in the latter group only 63 percent passed.

In an attempt to identify prognostic indicators, correlations were made between variables taken from the clinical history, psychometric tests and fear of flying questionnaire, and outcome on the pass-fail test. No important correlations emerged, although as a whole those who passed were older (41.5 versus 36.7 years). Their IPAT Sten scores,[1] MPI neuroticism and extroversion scores, and duration of phobia were remarkably similar at the beginning of treatment. Those who passed showed a consistent but statistically nonsignificant trend to more improvement in the psychometric test scores than did those who failed. It should be noted, however, that these scores were initially close to the normative scores for a similar population.

[1] A conversion of raw scores to a 0–10-point scale.

DISCUSSION

The three behavior therapy techniques seem to have been equally effective in significantly reducing air travel phobia. Group psychotherapy, by comparison, was quite ineffective at the termination of treatment, although at follow-up the differences among the four groups were no longer significant. One may assume that the behavior therapies achieved a more immediate result because they are more directly symptom-oriented. Their beneficial effect on the phobia is more readily realized by the patient, who then no longer avoids air travel. In contrast, the effect of group psychotherapy seems to develop slowly because it is only indirectly oriented toward the specific symptom. It deals with the historical antecedents and sources of anxiety, of which air travel phobia is only one manifestation. Insofar as the effect of group and perhaps individual psychotherapies is concerned, one may speak about an incubation of effect similar to the incubation of fear (phobia) that develops after a traumatic experience.

The lack of a significant difference between the results of sytematic desensitization and aversion relief therapies was not unexpected, since similar findings were obtained from a clinically more severely phobic population (10). What was perhaps unexpected was that habituation therapy—where neither aversion relief nor relaxation was used to lessen fear—proved as effective as either systematic desensitization or aversion relief. This is in contrast to the ineffectiveness of habituation in the treatment of phobic (primarily agoraphobic) neurosis (15). Perhaps the difference in outcome was due to the difference not only in type of phobia but also in initial anxiety levels. The air travel phobic subjects who received habituation therapy had a mean IPAT Sten score of 6.9, while the agoraphobic subjects had a mean Sten score of 8.0—a nonsignificant but important difference. Lader and Matthews (16) observed that while habituation of the orienting response occurred when the subject's anxiety was low, augmentation of the response occurred when the anxiety level was high.

In planning treatment, perhaps another important variable is the duration of the exposure to the phobic situation in the laboratory and/or in life. Experiments concerned with the reinstatement of fear (17) demonstrated a curvilinear relationship between the length of exposure to the fear-provoking situation and the magnitude of the fear response. At shorter exposure times an increase in duration led to an increase in fear, while at longer periods of exposure, a decline and, finally, extinction of the fear response occurred. Longer exposure time led to a reduction of phobic avoidance in cases of specific phobias (18). In contrast, prior to treatment our subjects did not report less anxiety at the end of a long flight (e.g., Montreal to Israel) than at the end of a shorter flight (e.g., to London

or Miami). Extensive previous flying experiences indeed tended to reduce benefit from the treatment. A primary but as yet unknown factor is the interaction between anxiety level and exposure time. Total phobia and multiple phobias were not predictive of poor treatment results.

Some reports (19) have questioned the necessity of relaxation in the desensitization of phobias, and one wonders what the effective ingredient in any of the behavior therapy techniques is. A parsimonious theory would suggest that repeated exposure to the sight and sounds of a flying experience while in a safe environment and exposure to fear in small, controllable doses, with the option of interrupting the experience at will, reduces the anxiety attendant upon the flying experience.

DISCUSSION

JOHN M. RHOADS, M.D. (Durham, N.C.)—Dr. Solyom and his associates present an interesting study of the treatment of 40 patients who suffered from phobic neurosis and who had in common a fear of flying. They compared the efficacy of four methods of treatment.

Air travel phobia is quite common, as anyone can tell by standing around in an airport and watching people pop pills before boarding airplanes. It would be interesting to compare the cost of the pills taken by a person who is required to travel by air frequently with the cost of eight hours of behavior therapy. Considering the high recovery and improvement rates and the fact that flying can be a reasonably pleasant or at least a neutral experience, as compared to an unpleasant or frightening one, I would think that the cost of the behavior therapy would be well worthwhile.

The failure of group therapy is not surprising, since treatment of this problem is not what group therapy is best for. An additional factor contributing to its failure may have been that a negative expectation on the part of the group therapist was communicated to the patients. As the authors note, group therapy may be useful in preparing patients for behavior therapy as, for example, in the study by Birk and associates (1), which involved aversion relief treatment of homosexuals following a year of group therapy. In a case such as that, group therapy is more nearly in its element, that is, in dealing with characterological problems and with relationships among and between people.

This paper once again demonstrates that the therapy of neuroses need not be related to eliciting their origins. While the authors don't dwell upon it, and in fact don't even mention it, it seems clear that they accept the idea that once a neurosis begins, it develops an autonomous life of its own and can be treated as an independent entity.

The authors ask why behavior therapy works. They suggest that when the patient is repeatedly exposed to the triggering stimuli in a safe environment and has the option of interrupting the experience at will, it reduces his anxiety. This is an interesting idea and suggests that what perhaps occurs is a regaining of control by the patient—a control almost entirely lost in the case of a phobia. Perhaps some of the failures of behavior therapy are thus related to the problem of whether the person has enough motivation to want to gain control or whether in some perverse way he is relatively content with his distress.

The study offers further conclusive evidence of the efficacy of different types of behavior therapy for the treatment of phobic neuroses.

Cheap Labor from Poor Nations

BY E. FULLER TORREY, M.D., AND ROBERT L. TAYLOR, M.D.

In the authors' opinion, one of the most serious problems facing American psychiatry is the importation of large numbers of foreign medical graduates to staff the country's mental hospitals. This paper reviews the magnitude of the problem, the utilization of these doctors as "cheap labor," the quality of care provided, and the effects of the "brain drain" on the countries of origin. It discusses possible roots of the problem and suggests some solutions.

A RECENT ISSUE of *Psychiatric News*, the official newspaper of the American Psychiatric Association, contained a remarkable letter. It was from a psychiatrist who advocated increasing the loopholes for using nonlicensed foreign doctors in state mental hospitals. The rationale given was that the only American psychiatrists he had been able to recruit had turned out to be alcoholics, drug addicts, or otherwise seriously disturbed and therefore that foreign doctors were certainly to be preferred (1).

This letter affords a capsule summary of a serious problem facing American medicine in general and American psychiatry in particular. It is the problem of having to import large numbers of foreign doctors to staff our hospitals for the mentally ill. There are indications that these doctors are used primarily to staff public institutions, that some of them may not provide as high a level of care as their American-trained counterparts, and that they are badly needed in the countries of their origin. This paper discusses the problem and offers some solutions.

While there are no absolute figures on the number of foreign medical graduates being used in American psychiatry, there are some indicators. In American medicine generally it is known that approximately 8,500 foreign medical graduates enter the United States each year; since 1967 the number entering annually has been greater than the total number of doctors graduating from U.S. medical schools (2, 3). It is also known that in 1970 there were 3,016 foreign medical graduates who were given licenses to practice permanently in the United States; these constituted 33 percent of all newly licensed physicians. In 1971 foreign medical graduates comprised over half of all new licensees in 13 states, and in two states (Maine and Delaware) they were more than 90 percent of all new licensees (4).

Specifically in regard to psychiatrists, it is known that during 1970, 34 percent of all psychiatric residents (1,370 out of 4,040) were foreign medical graduates (5). Of the 186 residency programs that were active, 28 were *completely* filled by foreigners. In fact, there were more psychiatric residents in American hospitals who had graduated from the medical schools of the University of Havana (77) or from the University of Santo Tomas in Manila (74) than there were graduates of *any* American or Canadian medical school (5).

One of the largest groups of foreign-trained doctors in American psychiatry rarely shows up on official statistics. These are the unlicensed doctors who practice in state hospitals using temporary permits issued by a state and valid only for state institutions. All but seven states have loopholes in their licensing laws that allow such temporary licensing. The permits are renewable yearly for an unlimited number of years. In New York and Ohio, 40 percent of the physicians in the state mental hospitals are unlicensed (6–8). In West Virginia it is over 90 percent (4). If 40 percent is a representative average for the United States, there would be approximately 3,100 unlicensed foreign doctors staffing state mental facilities in this country. One AMA spokesman estimated that the number is more like 7,500 (4).

FOREIGN PSYCHIATRISTS AS "CHEAP LABOR"

Foreign-trained psychiatrists work predominantly in those institutions which American psychiatrists consider the least desirable. Thus they are found in large numbers in city and state hospitals, prison hospitals, and institutions for the mentally retarded. Elmhurst City Hospital in New York City had 35 psychiatric residents in 1970, all of whom were foreign trained (5). State mental hospital residency programs depend very heavily upon them, as table 1 shows. Less than five percent of foreign-trained psychiatrists are in private practice in this country (9), in contrast to the more than 50 percent of U.S.-trained psychiatrists who are (10).

Theoretically foreign medical graduates are in residency training programs for training. But in fact such programs are often so burdened by the service needs of the state institutions that little time remains for any for-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this paper was written, Dr. Taylor was also with NIMH; he is currently Mental Health Program Chief with the Department of Health Services, San Rafael, Calif.

The views of the authors do not necessarily represent those of NIMH or the United States Public Health Service.

mal training. If the foreign graduate is unlicensed, he may be confined to the state system that has granted him his temporary permit until he can pass the state licensing examination. Some states also use psychiatric residency slots as administrative mechanisms for hiring foreign doctors at a lower salary than a full staff position would require, or when no full staff positions are available. This may help to explain why in 1971 at least five foreign-trained psychiatric residents were over the age of 60; two of these were 69. Such residents can presumably receive both a stipend for training and Social Security retirement benefits simultaneously.

Because of their concentration in public institutions, patients who cannot afford private psychiatric care are more likely to be treated by foreign-trained psychiatrists. Table 2 indicates this pattern. The cost of hospitalization in an institution like the Columbia Psychiatric Institute in New York or Timberlawn Hospital in Dallas may be as high as $3,000 a month; the state hospital is of course free if the patient has no money. This is consistent with other aspects of American psychiatry and can be summarized by Arnold Rogow's observation: "Perhaps the only firm conclusion is that Americans, in general, receive the psychiatrist and the psychiatric treatment *not* that they deserve, but that they can pay for. . ." (11).

TABLE 1

*Foreign Medical Residents in Selected State Hospital Systems, 1970**

State	Number of Residency Programs	Total Number of Psychiatric Residents	Foreign Medical Residents	
			Number	Percent
New York	18	211	198	94
Rhode Island	1	11	10	87
New Jersey	5	38	33	87
Massachusetts	7	51	41	80
Connecticut	3	46	37	80
Ohio	5	86	67	78
Maryland	3	22	17	77

*University hospitals that are state supported are not included in the calculations since they usually do not accept patients for long-term care.

THE QUALITY OF CARE

The majority of great ideas and advances in psychiatry have come from foreign-trained psychiatrists. Kraepelin, Freud, Jung, Adler, and many others not only were trained in foreign institutions but made their major contributions in foreign countries. Thus there is nothing inherently inferior (or superior) in being foreign-trained; rather, it depends solely upon the individual psychiatrist and his specific training experience.

It is likely that many leaders of American psychiatry will emerge from among the large influx of foreign psychiatrists coming to the United States. However, there are also indications that among the foreign-trained group there are some whose level of psychiatric expertise is not up to generally accepted American standards. This is seen most readily among a few of the unlicensed doctors, such as the doctor in a New York State mental hospital who was successfully sued for neglecting a fatal subdural hemorrhage (12) or the alleged doctor in an Illinois mental hospital who was recently charged with reckless conduct for the treatment of three patients who died (13).

The majority of foreign medical schools offer little or no psychiatric teaching to medical students. When they graduate, these doctors often arrive in the U.S. for a psychiatric residency with less knowledge of psychiatry than most American trainees at the same level. If the residency is in a hospital with a heavy service commitment, such as a state hospital, the resident will find it even more difficult to catch up.

Language difficulties compound the problem. Psychiatry, in contrast to radiology or pathology, is the medical specialty in which communication between the doctor and the patient is absolutely essential for adequate diagnosis and treatment. Equally important are possible cultural differences and the lack of a similar world view between doctor and patient. Imagine the difficulty, for instance, of a psychiatric resident from Korea trying to assess the mental problems of a drug-abusing American adolescent who is undergoing an existential crisis. In the light of such communication barriers a statement made by the director of mental hygiene in Ohio is slightly odd. In announcing special basic English courses for doctors in the state mental institutions he said: "I hasten to point out that we seldom hear a complaint that our foreign doctors are not providing adequate care and psychiatric treatment for their patients. The complaints center only around the inability to communicate" (14).

There are objective indicators that American psychiatry may not be attracting the best of the foreign medical graduates. One such indicator is the examination of the Education Council for Foreign Medical Graduates (ECFMG), an examination offered to medical graduates all over the world as a measure of their medical knowledge. It is made up in such a way that 98 percent of American medical graduates taking it for credit pass it. When it is given to medical graduates all over the world, only 40 percent of them pass it. Looking specifically at the pass rate for the eight foreign medical schools that contributed the greatest number of residents to American psychiatry in 1970, only two attained the worldwide average of 40 percent or higher (2). The two medical schools contributing the most psychiatric residents (the University of Havana and the University of Santo Tomas) had pass rates of only 20 and 13 percent, respectively. Similarly, on state licensure examinations the graduates of these two schools scored below the average pass rate of 63 percent for all foreign medical graduates. This in turn is considerably below the pass rate of 91 percent for American medical graduates (2). Four foreign medical graduates actually failed state board examinations for the 13th time during 1970. Between failures, such individuals may remain employed in state hospitals in most states on temporary permits.

In order to fully assess the quality of care offered by

psychiatrists who have been trained abroad, a careful clinical examination would have to be given. At present, this has not been done. In fact, it is quite conceivable for a foreign medical graduate to come to the United States and become fully licensed to practice psychiatry without ever being tested on his psychiatric knowledge. The examinations that he must pass (the ECFMG and a state board) have very few questions on psychiatry, and his residency program may never examine him formally.

THE "BRAIN DRAIN"

The other major consequence of using large numbers of foreign psychiatrists as cheap labor for the United States is the effect this has on the countries from which the foreign doctors come. This has been referred to as the "brain drain."

The countries that contributed the greatest number of psychiatric residents to the United States in 1970 (15) were the following: the Philippines—149 residents, India—136, Korea—107, Cuba—95, Argentina—55, Colombia—46, Iran—39, Mexico—25, Egypt—19, and Pakistan—19. This list corresponds with the frequently cited estimate that 85 percent of our imported medical manpower comes from underdeveloped countries.

While it is often said that the Philippines produces more doctors than it needs, this is not true. Only Manila and the other large cities are oversupplied with physicians; the remainder of the country has a low doctor-population ratio (16). Yet Filipino doctors are continuing to come to the United States in large numbers. The number of medical graduates taking the ECFMG in Manila is now so large that a football stadium has to be used to accommodate them for the examination (3).

Korea is another country that has been hit especially hard by the flow of trained doctors to the United States. In the past 20 years 23 percent of its physicians have departed, and only 3 percent have returned (17). Recently 90 percent of the graduates of one Korean medical school left Korea for U.S. internships; this same year there were 65 vacant internships in Korea. Korea, it should be noted, has a doctor-population ratio outside the capital of 1 to 17,000; the United States has a ratio of 1 to 700.

Overall it is not known how many of the foreign medical graduates who come to the United States for psychiatric training return to their homelands, but it is agreed that the returnees are a minority. A study of psychiatric residents from Mexico in the United States showed that 46 percent of them eventually returned to Mexico (18). A

director of a training program staffed predominantly with foreign residents found the return rate to be much lower: only two of his 34 foreign psychiatric residents from developing countries had ever returned to their homelands to practice (19). Furthermore, even for those who do return, it may be questioned whether the quality of their training experience has been appropriate for their country's needs on their return home.

It is known that taking this medical manpower from other lands saves the United States a large amount of money. If the 3,016 foreign doctors who were permanently licensed in the United States in 1970 had to be trained in the United States, they would require the addition of 30 new medical schools. To build a medical school costs at least $50 million and to operate one for a year averages $3.8 million (3). Thus the total amount needed to replace the foreign-trained doctors who were permanently licensed last year would be $1.6 billion. This is the equivalent of over half of the total U.S. foreign aid program. When this amount is added to other aspects of the brain drain, it may well be that our foreign aid program is in effect canceled altogether.

HOW THE PROBLEM CAME ABOUT

It is useful to inquire in retrospect how it developed that the United States is finding it necessary to import large numbers of psychiatrists from poor nations to staff our public mental institutions. Understanding the roots of the problem may be an initial step toward correcting it.

First it should be noted that a conscious conspiracy to take doctors from poor countries does *not* exist. Conspiracies imply planning, and anyone familiar with the inner workings of American psychiatry knows that this degree of planning simply does not exist. It is, in fact, the *absence* of planning that is closer to the root of the problem.

Who, then, is responsible for the absence of planning? Certainly not the foreign doctors themselves, who are only availing themselves of the best opportunities to further their careers and their livelihood. Indeed, how many American psychiatrists can say that they would not move to Manila to practice if they were offered a salary ten times what they are making here? Nor can public mental hospital administrators be held responsible; they are just trying to carry out their mandate to secure psychiatrists for their staffs.

Planning for the needs of American psychiatric manpower theoretically rests with the federal government (through the National Institute of Mental Health and the Bureau of Health Manpower Education) and with the professional associations (the American Medical Association and the American Psychiatric Association). We believe that none of these organizations has done a satisfactory job of planning; this is the root of the problem.

The National Institute of Mental Health has supported the training of psychiatrists since World War II, until recently at a rate of $40 million a year. Yet during this time it has made virtually no effort to ascertain what the psychiatrist was doing once he was trained. If it had gathered such data, it might have instituted a period of mandatory public service for psychiatrists who had been trained with public money. This would have ensured some psychiatric manpower for public institutions rather than allowing the psychiatrists to go immediately into private practice.

Similarly, the Bureau of Health Manpower Education has concentrated too much attention on increasing the total number of doctors and too little on the geographical distribution of the doctors. The myth has been that if the total number is increased sufficiently, there will be enough to go around. This is apparently not true. In the Philippines, for instance, there is an excess of doctors in the capital city, but the excess doctors have been found driving taxis and taking other jobs rather than leaving the capital to practice medicine in rural areas, where they are badly needed. It may well be that the United States already has enough doctors (and particularly psychiatrists) for its overall needs, if they were distributed more evenly. Our 25,000 psychiatrists constitute almost one-third of the world's total. Certainly many European countries are providing superior public psychiatric services with a far lower psychiatrist-population ratio than we have.

The American Medical Association has been doubly shortsighted. For many years this organization denied the existence of an impending doctor shortage. More recently it has acknowledged that there is a shortage, but has reacted only by trying to increase the absolute numbers without attempting to affect the geographical or specialty distribution. The American Psychiatric Association has made these same errors and has assumed that increasing the number of psychiatrists would somehow improve public service.

Both of these professional organizations may also be faulted for rigidly upholding outmoded standards that require a person with a medical license (i.e., a psychiatrist or other physician) for many jobs in public mental institutions that could just as satisfactorily be done by a person without a medical license (i.e., a psychologist, social worker, or nurse). Similarly, it is the combination of these two organizations that has accredited the state hospital residency "training" programs, which are training in name only and really are means of obtaining service personnel.

The U.S. Immigration Service and the State Department have compounded the problem of foreign doctors coming to this country. The liberalized immigration laws enacted in 1962, 1965, and 1970 made it increasingly easy for doctors to both come to and remain in this country. These liberalizations in the laws were made despite hearings warning against them in the Senate in 1967 (before the Senate Subcommittee on Immigration) and in the House of Representatives in 1968 (before the House Committee on Government Operations). Even prior to that (in 1966) Senator Walter Mondale raised his voice on the Senate floor and called the brain drain "a national disgrace" (20). Simultaneously the State Department was compiling a report attempting to deny that any brain drain problem existed (21).

The problem is also due to lack of planning in the developing countries themselves. By not setting up training facilities in their own hospitals, by often retaining a promotion system based on seniority rather than ability, and by permitting their doctors to leave before they have repaid their public-subsidized medical training with public service, the developing countries have encouraged their doctors to permanently emigrate to the United States and other countries.

SOME SUGGESTED SOLUTIONS

The problem of having to import large numbers of doctors from poor nations to staff our public mental institutions is a very serious one; it demands a solution. The following are suggested directions that could be pursued:

1. *Functional job analysis.* Psychiatry is going to have to do some hard thinking and functional job analysis on the tasks that psychiatrists are currently doing. Exactly what kind of training does one actually need to treat persons who are mentally ill? Do we really believe that an Iranian or a Korean psychiatrist, because he is a psychiatrist, is more effective than an American clinical psychologist in treating an American patient who is mentally ill?

2. *Public service.* American psychiatrists who are trained with public money should be expected to repay their debt with a period of public service and not just go directly into private practice. A loan system to replace present stipends would be one way to bring this about.

3. *Accreditation.* A system of mandatory accreditation is needed for every psychiatrist and psychiatric training program. This would help screen competent psychiatrists from those who are not competent (22).

4. *Separation of training and service.* In order to make all psychiatric residency training programs into *true* training programs, they must not be based on service needs. The service needs of public mental institutions must be filled apart from any training programs taking place there. Until this is done it is inevitable that some training programs will be merely facades for delivering services through the use of less expensive personnel. And if the trainees themselves are allowed to define how they want to achieve their training goals, one has the beginning of a true system of education (23).

5. *Improved training abroad.* It is possible to improve the training of doctors in their home countries so as to obviate the necessity for many of them to come to the United States on what become one-way trips. For instance, television and communications satellites will soon be available for long-distance teaching. Another possible use of modern technology would be to hook up computer outlets in other countries to an information and retrieval system in the National Library of Medicine.

6. *Specialized training programs.* There should be specialized training programs in which psychiatrists from abroad would come here to learn specialized skills and then return to their own countries. These programs would emphasize aspects of psychiatry that are appropriate for the developing countries. An excellent example of what can be done along these lines is the program for Indonesian psychiatrists set up at the University of Hawaii under Dr. John McDermott.

7. *Changes in the immigration laws.* Finally, there would have to be changes in the immigration laws so as to make it more difficult for foreign doctors to stay in the United States.

We recognize that solutions which include such things as obligated public service in exchange for public training and mandatory accreditation for individual psychiatrists are in conflict with the inclinations of many American psychiatrists. These are, it is said, contrary to the free enterprise model. We do not think that this is necessarily so. Benjamin Rush was both the father of American psychiatry and a signer of the Declaration of Independence. It is doubtful whether he saw a free enterprise system as meaning the freedom to take manpower from poorer countries in order to provide public services in wealthier ones

We also recognize that these solutions are not simple. But then, neither is the problem. American medicine in general, and American psychiatry in particular, are currently so dependent on foreign doctors that to suddenly remove them would precipitate a collapse of the whole system.

Solutions must be found. We should move rapidly toward a point when no longer would one find vignettes like one recently published in *The Washington Post* on conditions at the state prison in West Virginia. The article described the need for professional help for the inmates and mentioned that there *is* one psychiatrist "but he is a Cuban and does not speak English" (24). American psychiatry should be able to do better than this.

DISCUSSION

ROBERT CSERR, M.D. (MEDFIELD, MASS.)—To begin with a very unambiguous statement regarding this paper, the authors have portrayed the problem of foreign-trained physicians very accurately. They are telling it as it currently is, although I wonder at their figure of 50 percent of American psychiatrists being engaged in full-time private practice. The impressions that foreign-trained psychiatrists work in settings (usually institutional) that U.S. psychiatrists consider the least desirable and that "training" for them is often really a euphemism for "service work" because of the absence of real supervisory concern for their assimilation of knowledge are unfortunately very accurate in many instances.

Certainly, as the authors point out, there is no reason to feel that the quality of care per se delivered by a foreign-trained psychiatrist need be inferior to that delivered by his U.S.-trained counterpart. But with the two-class system of psychiatric training supported in this country, this frequently represents reality. What seems to prevail for foreign physicians, therefore, is: 1) their use (or misuse, as the case may be) as primary service-deliverers, although they are said to be in training, and 2) their general inadequacy, because of the lack of special attention to their needs, for the American psychiatric scene.

I would like to discuss these two issues and the specific approaches we have undertaken at Medfield State Hospital to deal with them; some of our work seems very much in consonance with the spirit of this article. First, to insist that only physicians are capable and effective in the areas of evaluation and treatment is unmitigated foolishness. At Medfield we have been able to remove all residents in training from the area of primary delivery of services by creating a cadre of clinical case administrators (paramedical professionals and preprofessionals), through whom the service needs of the patients are met. Supervision of these case administrators is by a group of experienced professionals, including psychiatrists. Residents have a bona fide training program: the service they give, although frequently extensive and valuable, is incidental to and a part of their training. This approach has indicated to us quite unequivocally the direction in which we must move to increase the extent and quality of services—namely, the training and employment of these other professionals and preprofessionals.

Second, special attention must be paid to the background and needs of the physicians-in-training from developing nations. There must be a flexible curriculum that includes subjects relevant to their needs, so that they can function as psychiatrists both in the U.S. setting and in their own nations after their training is completed.

The New England Psychiatric Society recently surveyed the problems concerning foreign-trained psychiatrists in our area. Dr. N.S. Mittell, Medfield's director of residency training, headed a task force that developed a recommendation to create an ombudsman to help foreign medical graduates get through the developmental crises that confront them in adapting to American society and psychiatry. The ombudsman would also attempt to ameliorate the numerous irrational harrassments facing these physicians.

I would now like to comment on the authors' proposed solutions of the problems concerning foreign medical graduates; I agree with some but disagree philosophically with others.

Certainly far too much public money has been spent on training psychiatrists who immediately move into the private sector with little recognition of their obligation to the public sector for subsidizing their training. But the attraction, both in terms of financial reward and in the opportunity to work with relatively more gratifying and less troublesome patients, is an overwhelming inducement. However, this is only one factor. I shall discuss another—the negative attitude prevailing in many state hospitals—shortly.

Surely some arrangements can be made incorporating the concept of universal conscription for a limited period of time for those trained at the public expense; this could even include the military as a "public institution" in which professionals could meet their obligations. However, I would strongly disagree with any plan that would definitively and perhaps permanently deprive any person, including a physician, of the freedom to practice his profession or trade where he wants. Such a policy would ultimately have devastating effects on the quality of the trade or profession. Although the authors do not say so explicitly, I am left with the uncomfortable feeling that, in their frustration, the authors are suggesting that, in order to ameliorate the situation in which foreign physicians are impressed into "slave-service" labor in public hospitals, U.S. psychiatrists should be treated in the same repressive way—then all would be equitable. This would hardly be a solution; in fact, I would expect this approach to compound the already indefensible situation present in so many of our public institutions. I would like to recall the approach I mentioned earlier: the greater use of other professionals and preprofessionals, which seems very much in accord with the authors' ideas.

In addition, I want to stress a very important issue that the authors seem to have neglected—namely, the conditions in and attitudes of many public institutions, which allow and indeed encourage poor care and care givers. Certainly the feudal attitudes on the part of the administrators of many public institutions hardly provide an incentive to anyone to find newer and better ways of rendering service. A dismal attitude on the part of professionals in public service, and in the private sector as well, has been shared for a long time by the community, which makes the job of change far more difficult but at the same time far more challenging and potentially rewarding. No amount of "quota-ing," in-country or out-of-country, is going to solve what is essentially a philosophical and attitudinal problem; only the people in charge of the institutions can begin to do that. Public institutions, including state hospitals, must change their philosophies and attitudes drastically so that an air of

rejuvenation rises from the old edifice, so that it becomes an exciting place to be rather than a warehouse, so that its considerable resources are deployed in active treatment, not as a home for the persona non grata. In the process of this transformation, improved training, both abroad and in this country, perhaps subsidized by both governments, can be developed. The obligations to their own country and to the United States that must be met by the resident-in-training can be specified. Rather than using the U.S. society as a prototype, the specific needs of developing nations might be considered in the training that foreign psychiatrists receive, both in the United States and in their own countries.

But the development of all this will have to be based on a change in attitude, not on military discipline. Many of the problems relating to foreign-trained physicians in second-class settings, where they are employed as "cheap labor" while ostensibly in training, would cease to exist if the second-class settings themselves moved with conviction toward becoming first-class. In addition to the resources currently available to them, they would need a great deal of imagination and daring and much more hard work. This is the approach we are using at Medfield State Hospital; it seems to be working.

It would be well for me to point out in conclusion that there are many paths for a career in psychiatry; that public and private service can and ought to coexist and that working with severely deprived or ego-damaged individuals is quite different from working with gifted individuals to further develop their considerable potential. (The two poles seem, at times, to be equated with public service and private practice, respectively.) Certainly both of these tasks are important; I will not debate which is more valuable to our society as a whole, although the latter will continue for a time to be compensated better, both financially and in terms of prestige, until some effective counter-compensations emerge. These counter-compensations are what I alluded to when I talked about change as a foundation for a public institution program. Psychiatry must become aware of the reality of the position it is finding itself in today with regard to the demands for and expectations of service. It must not move to either extreme—to the public sector at the expense of the private or to the private sector at the expense of the public. Either extreme, as with human beings and their behavior, brings forth trouble, which we call pathology. Certainly psychiatry should be able to reconcile the disparate elements of its feelings and behavior better than that, and further both public and private programs without resorting to extremism.

Answers to Questions of the Month

Foreign Medical Graduates: A Symposium

MILTON H. MILLER, M.D., FIKRE WORKNEH, M.D., EUGENE B. BRODY, M.D., DAVID J. LEWIS, M.D., AND TSUNG-YI LIN, M.D.

A session of the annual meeting of the American Psychiatric Association in Dallas, Tex., on May 2, 1972, was devoted to "Foreign Medical Graduates." Those presenting papers were members of the APA Task Force on Foreign Medical Graduates.

The participants were:

Milton H. Miller, M.D., Professor and Head, Department of Psychiatry, University of British Columbia, Vancouver, Canada, speaking on behalf of himself as chairman of the task force and of his associate, Tsung-yi Lin, M.D., Professor of Psychiatry and Professor of Mental Health, University of Michigan, Ann Arbor, consultant to the task force.

Fikre Workneh, M.D., formerly resident in psychiatry, University of Wisconsin, Madison, now Assistant Professor of Psychiatry, Haile Selassie University, Addis Ababa, Ethiopia, speaking on behalf of himself and his associates: Marjorie H. Klein, Ph.D., Assistant Professor, Department of Psychiatry and Psychiatric Institute, University of Wisconsin; Milton H. Miller, M.D.; Aris Alexander, Ph.D., Associate Professor, Department of Psychiatry, University of Wisconsin; and Kwo-hwa Tseng, M.D., Child Psychiatrist, Winnebago State Hospital, Oshkosh, Wis.

Eugene B. Brody, M.D., Professor and Chairman Department of Psychiatry, and Director, Institute of Psychiatry and Human Relations, University of Maryland, Baltimore, Md.

David J. Lewis, M.D., Professor, Division of Psychiatry, University of Calgary, Alberta, Canada, and Clinical Director, Department of Psychiatry, Foothills Hospital, Calgary.

Tsung-yi Lin, M.D., speaking on behalf of himself and of his associate, Mei-chen L. Lin, A.C.S.W., Social Work Supervisor, Children's Psychiatric Hospital, University of Michigan Medical Center.

Their papers are abstracted below.

An Introduction: Even Psychiatry Isn't Perfect

BY MILTON H. MILLER, M.D., AND ASSOCIATE

PSYCHIATRY IS PAINFULLY DISCOVERING another of its own neglected minorities, one now claiming a greater share of professional attention, resources, and understanding than it has currently been receiving. That minority is the group of foreign medical graduates (FMGs)—those training in North American residency programs and those who work in our psychiatric health care delivery systems. These physican colleagues are by no means a small minority. It has been reported that approximately one-third of all psychiatric residents in approved training centers are FMGs (1). Indeed, approximately ten percent of approved psychiatric training programs are staffed exclusively with foreign residents.

Less well counted than the psychiatric residents are foreign-trained doctors with varying levels of formal psychiatric experience who are employed in state mental hospitals and in hospitals and schools for the retarded. In one state psychiatric system, over 90 percent of physicians working in public mental hospitals are FMGs, many of whom have received little psychiatric training. Experience makes it clear that a substantial majority of all FMGs training and/or working in the United States and Canada will not return home; they will remain indefinitely in North America.

A 1971 AMA study concluded: "The major differential growth rate of the physician population over the general population in the United States has been due largely to the influx of foreign graduates. An additional input into the North American physician population comes as well from an estimated 3,000 native born North Americans who are presently studying in foreign medical schools" (2).

Buried within these large numbers are innumerable and enormously complex personal, organizational, national, and international problems. At the personal level, a good many—possibly most—recently arrived FMGs feel resentful as to the nature of their personal and professional destinies in North America. Many discover that a majority of their North American colleagues feel: "You should go home!" or "If you have decided to stay, you can't expect to have it as good as those of us who are native-born, or who came long ago, or who are well established." The kinds of limited medical licensure offered foreign graduates in many states reflects the ambivalent sentiments of the host country. In response, many FMGs feel deep resentment, others resignation; perhaps in some there develops a kind of identification with the aggressor, with consequent self-effacement and guilt. Many physicians coming from Asia and South America wonder: "Would things be better for me in North America if I were an immigrant from Europe?"

More broadly viewed, it is probable that the influx of foreign doctors into the various North American health

care systems, by seeming to fill job vacancies, has served to prevent the desperately needed national confrontation with the question of the adequacy and priorities of our health programs. We have imported doctors rather than allowing the expansion of medical and paramedical training. Thousands of young Americans and Canadians have been denied a medical education because it has seemed cheaper to import medical resources from overseas. Meanwhile, one can only barely comprehend the meaning of "brain drain" to those developing nations exporting doctors at a time when they are beginning to attend to the health care needs of their own people. These problems are interrelated, complex, and terribly important. They call for study and remedy.

However, simplistic solutions together with pious pronouncements about other people's responsibility to return home are of little value. Such reactions, fortunately uncommon, overlook the maze of complex "pull factors" toward industrialized nations and "push factors" away from nations turbulent in the transition from agrarian poverty. Ultimate solutions will require a review and change of existing national and state laws governing immigration and medical licensing policy, a study of hospital recruiting practices, a consideration of the limited positions in American medical schools, the development and more effective use of paramedical specialists in North America, and more imaginative efforts to attain an equal distribution of medical manpower. Furthermore, in the several instances of home countries that make little or no effort to retain their own physicians or to seek their return, a change in such national policies must be sought. And of course we who are the "established" North American physicians must recognize that the FMG now in the United States or Canada was offered a place to train and a place to stay, if he or she so chose.

Of immediate relevance to psychiatry, the Board of Trustees of APA last year appointed a Task Force on Foreign Medical Graduates, which is currently exploring possible steps that could be taken by the Association, its district branches, state commissioners of mental health, medical school departments of psychiatry, and the FMGs themselves.

Overall, the task force goal is both to increase the profession's awareness of and responsiveness to the special needs of physicians newly arrived from overseas and to increase psychiatry's ability to fully utilize the special talents of the gifted foreign medical colleagues in our midst.

The Foreign Medical Graduate: The Alienated Minority of Psychiatry

BY FIKRE WORKNEH, M.D., AND ASSOCIATES

WHAT IS IT LIKE to be an FMG studying or working in a North American hospital? This paper describes detailed interviews conducted with ten foreign-born physicians in various medical residency specialties at the University Hospitals in Madison, Wis. In addition, briefer discussions were held with ten other foreign physicians. We found—as have previous authors—that cross-cultural living and working is always more difficult than the casual observer would believe. This is as true of foreign doctors working or studying in the U.S. as it is of the younger graduate or undergraduate student.

A number of FMGs arrive in North America with definite English language deficiencies. They are often competent in reading and writing the language but deficient in conversational English. This creates difficulties in the early part of their sojourn both with their colleagues and with their patients. Some doctors vividly described the pain of being on night call the first day after arriving in a totally unfamiliar setting and with an untested ability in conversational and medical English. The names of even the most commonly used drugs vary from one country to another. And beyond language, the hurried and informal setting of the American hospital often leaves the FMG at a loss in trying to cope with conflicting values and interpersonal relationships.

The egalitarianism (or pseudo-egalitarianism) that is found in American medical training centers often proves quite puzzling to the FMG. The doctor-nurse "game" in the United States poses frequent problems for him. All the physicians interviewed spoke about the nurses' "level of dominance" compared to the nurses in their own country. While most were highly appreciative of the nurses' competence, there was frequent resentment of the status nurses expected. In many instances this caused an estrangement between the doctors and their nursing colleagues. The kind of feeling about peer relationships held by some FMGs is shared by foreign students in other fields, who also see American women as aggressive, domineering, and threatening.

An additional problem for some FMGs centers around the relative roles of doctor and patient. Many FMGs are high in the social hierarchy in their home countries. They are not used to being questioned by patients; in their home countries they are often held less generally accountable for their actions. By contrast, almost all FMGs whom we interviewed reported that most of their American patients are knowledgeable about their diseases and take an interest in discussing their situations. Some FMGs found the doctor-patient parity difficult to cope with. In several instances, the negative attitude of the foreign doctor had to do with his fear of the threat of a malpractice lawsuit. Talking with patients was, in the FMGs' eyes, somewhat dangerous.

Many foreign students, particularly those from developing nations, tend to attend classes in the host country but to do most of their living and enjoying only in the company of fellow nationals or other international students. Encounters with citizens of the host country are limited to occasional exchanges of pleasantries. They lead a life that is separated from the American culture.

The frequently restricted cultural adaptation of the wives of the FMGs, particularly those from developing

countries, is also important but has attracted very little attention. A number of these women neither work nor study; their lives are characterized by even greater loneliness, isolation, and frustration than that experienced by their husbands. Their activities, carried on without much encouragement, center solely around their husbands and their children (if they have any). For many foreign doctors, their wives' unhappiness reinforces their own social isolation and leads to many disappointments about cross-cultural living. Some work this out by accentuating their observance of the traditional ways of home. One resident who had lived with his family in the United States for two years revealed that his wife spoke no English and had abandoned earlier plans to learn. As a result she isolated herself from all social contacts, refusing invitations of house-staff wives and hardly moving out of the house except in the company of her husband during his occasional free weekend. Her husband was thinking of asking his mother-in-law to join them so that his wife would not be alone.

What are the responsibilities undertaken when one invites an FMG to work or train in a North American psychiatric institution? The implications of an answer encompass not only the doctor, his patients, and the institution involved, they leave in question the kind of total health system that fails to delineate and meet its responsibilities.

A Preventive Approach to the "Problem" of Foreign Medical Graduates

BY EUGENE B. BRODY, M.D.

ADMINISTRATORS AND HEALTH EDUCATORS in the donor nations are keenly aware that they reluctantly support the health systems of their more affluent neighbors. During my recent stay as a Pan American Health Organization-World Health Organization consultant at the University of the West Indies, I heard repeated discussions about the economic wisdom of maintaining a medical school that loses 40 to 60 percent of its graduates yearly to England, Canada, and the United States. The dean's office of that school estimated that the emigration of 40 physician-graduates per year represents an annual contribution of at least $960,000 to medical care elsewhere. Besides money, certain professional and personal costs are involved. The World Federation for Mental Health has explored the relevance of graduate training in psychiatry in the United States, Canada, and the United Kingdom for students from developing countries. Its conclusions, summarized by Beaubrun (3), were: 1) despite the general relevance of basic psychiatric concepts and methods, much that is taught in advanced industrial nations has little relevance for students from developing areas, and much of importance is omitted; and 2) students who received most of their training abroad either remained abroad or were misfits if they returned to their native countries.

The FMG in North America often cannot plan his future with the certainty of his American colleagues. His decision to remain in the United States or to return to his native land is often made only gradually and in piecemeal fashion. He is painfully aware of the hostility he may meet at home from professors who, feeling themselves rejected by his going abroad, may deny opportunities to him if he returns. He may feel guilty in the knowledge that his basic education expended the scarce resources of a country he is not going to serve. He is occasionally uncertain about the political climate of his home country, and is sensitive to its economic hazards. As Lin and associate have emphasized (see below), the most thoughtful realize that the usefulness of overseas psychiatric training is uncertain because of the low priority of psychiatry in the medical and public health programs of developing countries and the lack of interest of traditional psychiatric leadership in dynamic and community psychiatry.

Underlying the resistance to returning home are historical differences between emerging or postcolonial powers and nations that have long been politically autonomous and industrialized. The cumulative weight of traditional medical leadership—resistant to change—may be associated with a long-established small élite perched on the shoulders of an economically deprived, largely illiterate population mass; wealth inaccessible to taxation because of its concentration in a few hands or produced mainly by agriculture and mining based on cheap labor does not contribute to medical education or service.

A number of efforts have been made to reduce the "brain drain" at the source. One type of solution, reflecting changes in the political climate, is the imposition of governmental constraints. As Beaubrun noted, the older Caribbean practice of "the export of residents for training is now stigmatized as 'the Colonial method' " (3). The Commonwealth Caribbean Ministers of Health have agreed to give precedence for career advancement within the region to holders of the higher degrees from the University of the West Indies in preference to those with foreign qualifications.

Another approach has involved the participation of home-country educators and health administrators in planning overseas training. A notably successful example was that of the department of psychiatry at the University of Taiwan under the direction of Professor Tsung-yi Lin. This fits the suggestion, growing out of the World Federation for Mental Health seminars, that the first two years of graduate training in psychiatry should be accomplished in the home territory before a resident goes abroad for advanced work. This establishes his mature identification with his own professional community.

But the most basic step is yet to be taken. This is the formulation of internationally recognized standards of psychiatric education for facilities, programs, and the products of these programs. Without such standards it becomes extraordinarily difficult to develop educational experiences capable either of reducing the need of young

people to seek training abroad or of giving them the necessary base for successful advanced learning in foreign centers. We propose as a first step the establishment of an Inter-American Commission on Psychiatric Education. This could operate under the auspices of the Pan American Health Organization of WHO, with the collaboration of the Inter-American Council of Psychiatric Associations, the World Psychiatric Association, the World Federation for Mental Health, and other key international and national groups concerned with medical education. The initial function of the commission would be to promote the interchange of information and ideas concerning psychiatric education in the hemisphere; the next task would be to arrive at mutual agreement about international standards and guidelines; this step might ultimately (but not necessarily) lead to international accreditation of psychiatric training programs and certification of graduate specialists.

The Treatment of the Alienated by the Alienist

BY DAVID J. LEWIS, M.D.

FROM PERSONAL EXPERIENCE, we are all aware that foreign residents have passed through an ordeal of strangeness and alienation from their own country and from themselves; they have also felt at a distance from their patients. The difficulties are expressed in different ways, depending on the stage of acculturation of the foreign resident.

Initially the crush of culture differences, the strangeness within the place of employment, and the difficulties attending interpersonal contact interfere by slowing him down and making him very dependent on unit leadership. This is especially true in the larger mental hospitals where most FMGs take their training; such training is frequently, although not always, deficient.

Following the period of initial culture crush—which could extend from several weeks up to three years, with a mode of about six months—the resident begins to take hold and to form ideas, often oversimplified, of the task required of him.

Some residents remain at this primitivist stage. They prescribe medication and physical treatment with little concern for the patient's underlying problems throughout their professional careers. Often these careers are very remunerative. Others fortunately develop a fine sensitivity to our country. Yet others never manage to make good their hopes and either revert to other specialties or accept inadequate posts outside the profession.

It is rare, although not absolutely unknown, to find foreign medical graduates in high-prestige positions. They continue to be subject to discrimination and sometimes to scapegoating on the basis of the general stigma against the foreigner and also because of misunderstandings resulting from mild, culture-caused misdemeanors or misadventures. A high degree of communication between the FMGs and those responsible for their efforts as supervisors and teachers is required, otherwise these victims defect or are extruded, often over rather picayune incidents.

Those residents who have been able to make long-term adjustments have more than justified the efforts taken to guide and support their earlier years. Foreign residents learn quickly and effectively from teachers but are often puzzled by differences in orientation between instructors. Their learning would be enhanced if structure could be imparted to their natural adjustment process. It is often a long series of chances and "happenstances" that governs the development of their careers.

By contrast to the present policy of muddling through, an example can be pointed out. Practically all of the individuals who have utilized the Colombo Plan in Canada to secure their postgraduate education have returned home to work in their own countries. On the other hand, those who come to the United States and Canada on their own do so wastefully in terms of years spent, opportunities offered and utilized, and affect deployed. The present wasteful situation could be changed without too much difficulty. For example, the APA Task Force on Foreign Medical Graduates has suggested a three-pronged approach, beginning with the study of the foreign medical graduate in our midst and in his homeland, proceeding to the establishment of pilot educational programs in suitable centers in the United States, and culminating in the establishment of international training programs. This should bring to the field of international medical education a greater degree of certainty than has so far characterized it.

It is felt that interactions could be greatly enhanced by commitments between authorities in the country of origin (both medical and governmental), the foreign medical graduate himself, and the institution at which his training is to be obtained. It would also be necessary to involve a world organization such as WHO that might make information about resources and needs available to the groups mentioned above. Demonstration projects and consultant personnel to governments and to foreign training centers are also important. If definite commitments were made by home units to take back staff members and to maintain an interest in them throughout their foreign stay, I believe we would avoid the wastage of personnel as well as the dislocation and distraction of health resources. In a word, we would substitute structure for the present anomie.

The Psychiatric Educational Background of Foreign Medical Graduates

BY TSUNG-YI LIN, M.D., AND ASSOCIATE

THE FMGs FROM DEVELOPING NATIONS who are in the United States psychiatric system today differ greatly in

many respects from the foreign psychiatrists who migrated from Europe in the 1920s, 1930s and 1940s. The former do not carry with them the cultural prestige or professional expertise of the latter, who came as a rule as specialists and/or teachers, usually from major centers of learning. Furthermore, the European group belonged to the same cultural and scientific circle before and after their migration. This group identity and cohesion, coupled with the fact that the majority even belonged to the same school of psychiatry (that is, psychoanalysis), helped to promote their professional advancement in the new world, which was more or less ready to absorb their knowledge and skills.

As Torrey and Taylor (4) have pointed out, the accumulation of FMGs in our psychiatric system has been caused largely by the need to fill positions not wanted by American residents or psychiatrists. This need is filled by FMGs, conveniently imported from abroad as "cheap labor." The long-standing two-class system of psychiatric services has thus been further reinforced; FMGs are used as the scapegoats of the rather ineffective, wasteful public psychiatric system.

Still, in our view the problem of FMGs merits neither pessimism nor despair. A concerted and systematic effort from all concerned, based on a clear understanding and the acceptance of the reality, is what is needed; we have no doubt that a good beginning toward a solution will then be worked out. The reality is that FMGs are here to stay and perhaps in increasing numbers. If the present "brain drain" and the health care delivery system remain unaltered, their presence will be increasingly important to the survival of public psychiatric institutions in the United States.

A clear understanding of the specific needs of any trainee, judged from an objective and sympathetic assessment of his educational background, is basic to the formulation of a relevant and effective educational plan. This also applies to FMGs.

Let us take a closer look at some of the facts and statistics that constitute the basis for some of the concerns about the quality of the FMGs. The passing rate on the Education Council for Foreign Medical Graduates (ECFMG) examination in 1969 was 34.3 percent (5). This certainly was a poor record. But with all fairness to the ECFMG, the passing rate should not be used as an index of the quality of a particular medical school or the medical education of a specific nation. The ECFMG applicants are not a representative sample of the graduates of a school or of a nation. In addition, language facility plays an important role in the scoring, and thus candidates from non-English-speaking nations are handicapped.

The low rate of those passing the ECFMG in their countries of origin should not be taken as an indication of the "inferior" medical training of the foreign medical graduates currently receiving training in the United States or Canada. These trainees passed the test in spite of their different educational background, in spite of the language and cultural barriers, and in spite of unfamiliarity with the testing method. Therefore one can even claim that the FMGs in training in the United States should be considered as physicians of considerable quality and people of potential who merit attention and assistance.

We shall now discuss the psychiatric educational background of FMGs in developing nations on the basis of two fact-finding surveys made by WHO. WHO conducted two conferences on "The Place of Psychiatry in Medical Education": one in Agra, India, in 1968 for countries in the Southeast Asia region, the other in Alexandria, Egypt, in 1970 for countries in the East Mediterranean region. Ceylon, India, Thailand, Indonesia, Burma, and Afghanistan participated in the first meeting and Lebanon, Pakistan, the United Arab Republic, Sudan, Ethiopia, Iran, Jordan, Tunisia, Kuwait, Iraq, and Syria in the second. Their primary purpose was to review current practices of teaching psychiatry and to determine the appropriate role of psychiatry in medical education in the countries concerned. The major findings of the conferences (6, 7) may be summarized as follows:

1. Psychiatry was indeed a seriously neglected subject in most medical schools; a large number of the schools offered no teaching in psychiatry at all. The most common type of teaching took the form of poorly organized mental hospital visits, supplemented by a few lectures given by part-time teachers who usually were on the staff of psychiatric hospitals. Only in a very few medical schools—e.g., in Indonesia, Thailand, Lebanon, and Sudan—was psychiatry taught by full-time faculty members as a regular course that had some resemblance to courses in developed nations.

2. The content of teaching in most medical schools seldom went beyond the demonstration of various types of psychiatric disorders and their diagnostic labels. Students were rarely given sufficient practical clinical experience to learn basic diagnostic or therapeutic skills for dealing with mental patients.

3. Rarely was psychiatry taught jointly with other branches of clinical medicine or social and preventive medicine. The isolation of psychiatry from the rest of medical education was further reinforced by the geographic location of the psychiatric facilities: usually a far corner of the medical center or a distant psychiatric hospital.

4. The total number of hours of teaching given to psychiatry throughout the six years of the premedical and medical curricula, including behavioral sciences and clerkship, ranged from 16 to 230 hours, with an average of 76.7 hours.

5. Only in a small number of medical schools was psychiatry taught as an independent subject requiring examination. In most schools examination in psychiatry was given as part of medicine or another subject, or no examination was required.

6. National and institutional variations were noticed. For example, a few medical schools in Thailand and Indonesia were giving more emphasis to teaching psychiatry. This was brought about by a more enlightened leadership in medical education or the work of a devoted psychiatric leadership (or a combination) eager to de-

velop mental health programs to meet community needs.

7. The place of psychiatry in the medical curriculum generally reflected the position of mental health programs in the national health plan. This is well illustrated by the fact that not a single mention of "mental health" or "psychiatry" can be found in the book *Health and the Developing World* (8), which contains one of the best analyses of the health problems in developing nations as well as many excellent recommendations for their solutions.

8. A most depressing observation was that the overall situation regarding teaching psychiatry in the medical schools of these countries had not improved significantly since the publication of an important WHO document (9) on the subject in 1960; this was written primarily for developing nations to stimulate new developments in psychiatric education.

It is therefore hardly surprising that the FMGs, with such minimal previous psychiatric education, should encounter serious difficulties in learning psychiatry in a resident training program in the United States. The omnipresent problems of language and acculturation handicap them further and make them appear, in the first or even the second year, as "fools" or "useless clinicians" in the eyes of their colleagues or even patients. A recent report (1), however, presented a different picture. The completion rate of FMGs in residency training centers was approximately 80 percent, while that of all the residents was approximately 82 percent. The figure for FMGs should be regarded as very praiseworthy, considering the problems facing them. Their courage, determination, and capacity for learning cannot be underestimated, although many other factors also contributed to their high rate of completion, such as financial reasons, immigration requirements, or job opportunities.

The success rate of FMGs in the American Board of Psychiatry and Neurology examination is reported as low (10). This finding can be looked at from various points of view. Again, one should not overlook an important point: a number of FMGs have succeeded in passing the Board examination in spite of their linguistic, educational, and cultural handicaps and in spite of their unsatisfactory psychiatric training (the majority of them take their residency training in state hospital systems, which are in general inferior to university or medical centers). Kolb was right in concluding that "there should be a greater equality in training opportunities for those who come here from abroad" (11).

If an FMG is placed in a state hospital that has no active treatment or rehabilitation programs, the hospital atmosphere and his clinical experiences will probably reinforce his bias and harden his inferiority complex as a "second-rate" physician. This will certainly affect his motivation for learning. If he is accepted as a resident in a university or medical center training program, the clinical training, emphasizing dynamic or social psychiatry, may be too overwhelming intellectually or psychologically (or both) unless he is exceptionally bright, articulate, flexible, hardworking, and reasonably aggressive. Often one finds in such settings a few FMGs drifting to laboratories or engaging in nonclinical activities. It is obvious that this kind of bias should be recognized and handled properly at an early stage in the training of FMGs. This also suggests the importance of American educators and administrators becoming aware of such problems and developing sympathetic attitudes and skills to handle them.

It is also evident that something must be done to help developing nations start vigorous mental health services to meet their mental health needs. As Waggoner stated, "The United States should accept the challenge of assisting other nations in developing their psychiatric programs" (12). There is no better or more effective way to do this than to assist these nations in acquiring a core of able, farsighted, and dedicated trained personnel as leaders for developing their mental health programs. A few shining examples of success are witness to the value of establishing psychiatric centers of excellence in the developing nations through well-planned, long-term international cooperation. Examples include the Taiwan-Harvard (Boston) model, the Jamaica-Edinburgh model, and the Malaysia-University of Washington (Seattle) model, among others. The APA Task Force on Foreign Medical Graduates also plans to initiate more such programs and to obtain the cooperation of the World Psychiatric Association, the World Federation for Mental Health, and WHO.

The sum and substance of what we have tried to decipher from the published and unpublished information is that the FMGs currently in the U.S. psychiatric system deserve attention and assistance in their professional growth. Although there may be deficiencies in their backgrounds, the picture is more favorable than commonly perceived.

DISCUSSIONS

THE DISCUSSION WAS OPENED by *Dr. Leonard Ganser*, Director of Mental Health for Wisconsin. He observed: "I have always been puzzled about our tendency to feel that it is we who are extending the privilege. The FMG who comes to us is much more often than not a gifted, ambitious person who brings many needed skills. We allow him to come, thereby extending a privilege. But if an American decides to work overseas, we feel: 'How lucky they are to receive him. How gracious of him to offer them the privilege of his presence.' "

Dr. Bernard Holland, Professor and Chairman of the Department of Psychiatry, Emory University, Atlanta, Ga., described as one of the basic ingredients in the picture "the many-year unwillingness of the United States to adequately pay for the medical education and advanced training of its own citizens. If we were obliged to recompense foreign countries the 30,000 or 40,000 dollars necessary to train the FMG who leaves his home country to come to the United States, it would be a more honest transaction. And such payment would bring home to Congress the fact that other countries are now paying the bill for a good part of our health care."

Dr. Jaime Smith e Incas, practicing psychiatrist in Columbus, Ohio, suggested: "It is simply good mental health for those responsible for health care programs to demonstrate not only remote awareness of the needs of FMGs but to initiate appropriate actions to look after the mental health of all those who work in the system. In this respect, there has often been a gross neglect of the feelings and attitudes and the need for a sense of well-being of the FMG. Yet the FMG is often very important in the operation of the health care system." He felt that the place of the FMGs should be acknowledged and dealt with, contrasting this with the present tendency to ignore and overlook their presence while using their skills.

Dr. Walter Shervington, Director of the Training Branch at NIMH, compared the current meeting with the meeting of the first Black Caucus of psychiatrists at an earlier APA meeting in Miami Beach. He felt that in many respects, the contemporary problems of FMGs were not without racial implications: "Based on past performances, a suspicious person might wonder whether the status of a profession of white and established doctors would be enhanced by a group of second-class doctors. And if so, that suspicious person might wonder how much effort the established doctors would make in changing the status quo."

Dr. Joel S. Steinberg, Assistant Professor of Psychiatry at Case-Western Reserve, Cleveland, Ohio, described his evolution in thinking about FMGs:

> Initially I was interested in the problem of the FMG because of the great importance of communicative skills in psychiatry. In my experience as a moderately skilled bilingual internist, I found myself at sea with many patients—not because I could not understand what they were saying, or because they couldn't understand what I was asking, but because, despite the adequate exchange of information, I often had difficulty in deciding what the exchanged information meant. It seemed to be more an internal problem—although the exchange appeared to be adequate content-wise, it was superficial and lacking the full-bodied information exchanged in English. I assume that were I truly bilingual, this apparent difficulty would not be manifest.
>
> My initial bias, then, as I joined the Task Force on Foreign Medical Graduates was that the fewer FMGs practicing in this country, the better for all parties concerned. This attitude would not solve the problems of those FMGs who are already here, nor their patients, nor would it help resolve our health manpower shortage. I learned that the FMG has many things to offer us—his energy, motivation, upwardboundness, his vision of us as an outsider, and other attributes. In short, he brings to us many of the advantages that immigrants have typically brought to America.

Dr. Carl H. Fellner, Professor of Psychiatry at the University of Washington, Seattle, described differences between the FMG who declares himself as a foreign student here as a guest for a limited time and the foreign student who declares himself as having come to stay:

> There is considerably more curiosity and interest toward the guest, a willingness to tolerate his being different and even to explore some of these differences with little prejudice. There is a considerable tolerance and acceptance of his or her deficiencies in knowledge, be they scientific or cultural or social. Often a good deal of curiosity is expressed about the guest's home country, his family, his society, his religious beliefs, his culture. Now all this changes quite radically as soon as the FMG has declared himself as an aspirant to becoming a permanent member of the host country, a permanent member of the professional group, the society, the town. His being different in so many ways no longer evokes sympathy or respect. His explanations and illustrations of the differences in his background, feelings, and opinions is in most instances met with a demand to discard these and to adhere to the standards of this country, this society, this group. He must, as has been pointed out by so many of the previous speakers, show proof that he is better, tries harder, gives more, and asks for less than the native colleague, neighbor, teacher, friend. These are very important matters that need in some way to be taken into consideration in devising a training program for the FMG.

Coping with Problems: Attitudes Toward Children Who Set Fires

BY CAROLYN N. WINGET, M.A., AND ROY M. WHITMAN, M.D.

As part of an environmental health survey, 300 urban adults were asked how they would deal with a child who set fires. Respondents who were young, of upper socioeconomic status, and with numerous interpersonal relationships and low degrees of alienation most frequently gave positive-constructive responses indicating the use of outside resources. However, only about one-third specified mental health professionals. The authors discuss the implications of these findings in terms of improved orientation of representatives of the official community as well as in decentralized and more easily accessible mental health centers.

AUTHORITIES IN MENTAL HEALTH view repetitive fire setting by children as a severe behavioral symptom requiring professional help. There is a modest literature on the etiology and intrapsychic dynamics of this symptom. Considerably less information is available about how the potential consumer of mental health services perceives the problem of fire setting by children or how he conceptualizes ways of coping with it. The purpose of this paper is to report upon one aspect of an investigation in which hypothetical mental health problems were presented to a stratified random sample of adults residing in a large midwestern city. Although the present study addresses itself to representative attitudes toward dealing with fire setting as one serious psychiatric problem of childhood, the findings may be generalized to larger issues in community mental health and the concomitant problems of health care delivery.

The psychiatric stance on the delivery of health care has essentially been derived from the traditional medical model. Two aspects of this model are especially pertinent. One has to do with the fact that effective preventive medicine, as illustrated by vaccines against smallpox and polio, for instance, has only become feasible when the problem has been defined and accepted as a difficulty amenable to solution. The other implication of the medical model is that the source of medical or psychiatric help is usually centrally located in medical office buildings or clinics and the potential patient must have not only knowledge of these sites, but also access to them in order to apply for assistance to alleviate his distress. The urgent need for continuing efforts in the definition and dissemination of information on mental health problems and for the exploration of different methods for delivering health care to people is illustrated in the data presented in this paper.

FIRE SETTING AS A PROBLEM IN CHILDREN

A recent article on this subject starts characteristically: "Firesetting in children is a serious symptom and is considered by many to be a valid reason for emergency consultation" (1). A survey of the literature on fire setting reveals that most of the articles deal with the phenomenology of the symptom, its symbolic meaning, its psychoanalytic dynamics, and some aspects of the treatment process. By and large, the child is referred for treatment by the school or the court, which, rather than the parents, sees the fire setting as a serious presenting symptom.

In her comprehensive study, Yarnell (2) reported that most earlier writers used as their starting points Freud's observations about man's need to gain power over nature by acquiring power over fire (3). As a consequence, the libidinal-sexual components of fire setting were emphasized and the important aggressive components of this behavior were often de-emphasized. Significantly, fire setting was rarely the complaint that brought a child to the attention of psychiatrists; rather, it was asocial or truant types of behavior other than fire setting, and the latter symptom was noted as an additional complaint. Two recent reports (1, 4) tend to confirm this finding. In addition, almost all studies since Yarnell's have emphasized that fire-setting behavior is multidetermined and that the aggressive element seems to be more prominent than the libidinal element (5–8).

There is a certain parallelism here with a current problem that our society is now facing and coping with poorly—that is, the handling of aggressive impulses, particularly on the part of minority and youthful populations—for the symptom of fire setting has both an internal psychodynamic reference and a sociological group reference. The rage and uncontrolled aggressive hyperactivity that lead to fire-setting behavior in children are also to be seen in the way fire has been used as a form of

protest by blacks and the radical left. It is not only destructive but vivid and dramatic in its intensity.

METHOD

Mental health questions were included in a general environmental health survey that was administered to a group of 300 respondents randomly selected to be broadly representative of the population of Cincinnati, Ohio. Details of this sample have been reported previously (9). The questions in the mental health portion of the survey were worded so as to require a cognitive solution to an emotional issue. Earlier national studies (10–12) focused on reality questions of etiology and sources of unhappiness, worry, and maladjustment, as well as actual ways in which people had coped with such problems.

Questions in this study were designed to approach these issues more obliquely, by posing hypothetical questions on anxiety, depression, suicidal tendencies, and fire setting. It was felt that some defensiveness on the part of the respondent could thus be circumvented and that the responses could provide an index of the extent to which mental health problems were recognized, as well as indirectly furnishing data on how knowledgeable various strata of the population were with regard to community mental health resources.

The environmental health survey questionnaire was a lengthy one, and the mental health questions were embedded at a point in the interview at which sufficient time had elapsed for some degree of rapport and mutual trust to have been established between interviewer and respondent. All interviews were conducted in the homes of the respondents by interviewers of the same race as the subject. The question on fire setting provided a dramatic problem to respondents and was chosen for its impelling quality to stimulate remedial action.

RESULTS

The specific question posed was: "If you had a child who repeatedly set fires, what would you do about it?" The key words are "repeatedly" and "fires," coupled with a challenge to solve the problem. Since this was an open-ended question, which the respondent might deal with in any way he chose, the range of responses was great. The most frequent response was "See a psychiatrist," which was given by one out of five respondents. About 15 percent of those in the survey sample said that they would seek help from a family doctor or a clinic doctor; an equal proportion said that they would not know what to do or felt they couldn't answer the question. References to clergy as a source of help had the lowest response frequency (less than one percent).

Responses were further categorized as follows:

1. *Positive or constructive responses.* This included any response that could possibly lead to suitable professional referral, including all references to psychiatrists, doctors, clinics, or other professional, community, or neighborhood resources if the reply was couched in terms of helping the child.

2. *Helpless or hostile responses.* These were responses that were directly punitive ("I'd burn him so he'd know better"), indirectly or covertly punitive ("I'd call in a policeman to give him a good scare"), and ambivalent ("I'd give him a good whipping and talk to my minister about it"). Also included here were "I don't know" or "I can't answer that" replies, on the assumption that the lack of responsiveness implied a lack of knowledge of how to deal with the problem.

3. *Controlling or neutral responses.* These consisted of references to police, fire fighters, institutionalization in a state hospital, or court commitment, unless given in a context of hostility and punitiveness. This class of responses also included control within the home ("hiding the matches" or "keeping an eye on him").

The results of this coding are given in the column headings of table 1. Analysis of the grouped data as summarized in table 1 revealed that a number of demographic and behavioral variables were significantly related to response patterns.[1]

1. *Race.* Negative responses were more frequent among whites (38 percent) than blacks (19 percent). Compared with whites, almost twice as many of the blacks gave responses that were coded as neutral.

2. *Age.* Almost 80 percent of those in the 21–34 age group gave positive-constructive responses. This proportion declined steadily for each age group to less than 25 percent of those 65 years of age and older.

3. *Socioeconomic status.* The higher the class status, the more likely that responses would be positive (68 percent) and the less likely that they would be neutral (four percent).

4. *Anomie.* Those who indicated a low degree of alienation from societal values and norms, as measured by a ten-item index (13), reported, proportionately, the most frequent positive coping methods and the least frequent negative responses.

5. *Affiliative behavior.* There was a consistent and significant direct relationship between the amount of self-reported interchange in formal and informal interpersonal relationships and the proportion of constructive coping responses.

6. *Sex and marital status.* These were not statistically significant factors, although there was a tendency for more of the women and more of the married respondents to respond with constructive ways of coping.

DISCUSSION

The main focus of this study has been an examination of the ways in which various segments of the general population might cope with a serious childhood psychiatric symptom. There are encouraging aspects to the findings.

[1] Detailed basic data may be obtained from the authors. The chi-square test with the appropriate degrees of freedom was used to evaluate statistical significance.

TABLE 1
Summary of Statistical Analysis of Grouped Data by Demographic and Behavioral Variables (N=300)

Variable	Responses to Question on Fire Setting						Significance
	Positive-Constructive		Helpless-Hostile		Neutral-Controlling		
	Number	Percent	Number	Percent	Number	Percent	
Race							p<.001

Average	84	62.2	34	25.2	17	12.6	
Low	39	37.1	47	44.8	19	18.1	
Total	163	54.3	96	32.0	41	13.7	

*Since three respondents refused to divulge their marital status, the total number for this analysis is 297 rather than 300.

If one combines all forms of outside resources named by respondents, over half of those sampled would seek some type of outside help; this is indicative of the high recognition of the seriousness of the problem posed by a child who repeatedly sets fires.

A less rosy picture emerges from a more realistic appraisal of how respondents themselves identified the outside help they would seek. If one thinks of psychiatrists and other professionals in the mental health field as the most constructive type of resource, about one in three persons would seek an effective solution. To the extent that police and other representatives of the official community are looked to for help and are not oriented to their roles in this referral system, the likelihood of constructive outcome is seriously diminished. The parallel with suicide prevention centers is quite striking. Essentially, those who are in greatest need are those least likely to be reached or to reach out.

We found reason to believe that the continuing efforts in mental health education have been successful. In particular, the highly significant findings with regard to the relationship of age to type of response should be encouraging to those who have worked at many levels of our society to broaden understanding of mental health concepts. Almost 80 percent of those under age 35 mentioned a constructive resource or method to be used for coping with a child who sets fires.

The finding of greater constructive effort by those with upper-middle-class status is consistent with what might be expected for those with more years of schooling, greater income, and higher occupational status. Two-thirds of the lower-class subjects gave responses indicative of outright hostility, helplessness implicit in a "don't know" response, and the probably ineffectual responses that we coded as "neutral." It seems likely that this group needs much more from society, both in terms of helping to define the dimensions of mental health problems and in the institutional changes that would make health care delivery more easily accessible both geographically and bureaucratically.

The area of greatest racial difference was that, proportionately, almost twice as many whites as blacks gave responses in the negative category (hostile or helpless). This would fit with the theory of some militant blacks who have asserted that blacks are kinder, more generous, and less punitive than whites. An alternative explanation may

be that blacks have a greater tolerance for deviant behavior than whites.

We have used the term "anomie" in Srole's sense to mean a feeling of alienation, lack of integration, or inharmonious relationship to society. Our finding that both anomie and affiliative behavior are significantly related to the types of responses to the fire-setting question is consistent with previous research indicating a negative relationship between measures of anomie and socioeconomic class (14) and between anomie and measures of social interaction and social isolation (15, 16). Langner and Michael (12) also reported higher mental health risks among those who were poor in interpersonal affiliations.

Migration and Psychopathology of Eskimo Women

BY JOSEPH D. BLOOM, M.D.

Various epidemiological studies have noted the high rate of migration of Eskimo women from their native villages into cities and large rural towns and also their higher rate of psychopathology compared to Eskimo men. The author explores both trends and correlates them, theorizing that the Eskimo woman's dissatisfaction with her low standing in the native culture provides impetus for migration in the hope of marrying a nonnative man. This uprooting, along with unsatisfactory integration into the new culture, may lead to increased psychopathology.

THE PURPOSE OF THIS PAPER is to examine certain possible differences between Eskimo men and women in terms of migration and manifest psychopathology. Available evidence seems to point to Eskimo women migrating toward urban areas more frequently than men and showing a greater number of psychopathological symptoms. I will offer explanations for and explore the implications of these statements in light of traditional Eskimo culture and personality development.

PHYSICAL MIGRATION

General Patterns

Little doubt exists that there is a general migration of young adults away from the smaller villages in rural Alaska. This can be shown by the relative absence of young adults in the smaller villages. Hippler (1) has shown that in a composite group of small Eskimo villages in northwest Alaska there were fewer individuals in the group ranging in age from 24 to 29 years than in the group ranging in age from 40 to 44. Although there may be many reasons for this finding (including a possible differential mortality pattern), one explanation would certainly be migration out of the villages.

Although the population of small villages has been shown to be persisting and even growing (2), there is clear evidence that the Eskimo population is also growing in the larger rural towns such as Bethel, Barrow, Kotzebue, and Nome and in the urban centers such as Anchorage and Fairbanks. Further, it is clear from the age distribution of village populations that the majority are composed of dependent children. For example. Hooper Bay, a Bering Sea village, had a population in 1966 of 535 people, of whom 52.9 percent were under 14 years of age, 19.5 percent were between ages 15 and 24, only 16.6 percent were between ages 25 and 44, and only 11 percent were over age 45 (3).

The large rural towns are thus growing both from their own population base and from substantial numbers of migrants from the villages. The reasons most often cited for people coming to these towns is desire for cash employment (although precious little is to be had) and for goods and services such as schools and hospitals, and the lure and excitement of living in a larger town. This latter reason seems to be particularly important to young adults (4,5).

Hippler (6) described the growth of the towns of Barrow and Kotzebue as representing the coalescence of smaller villages that are now almost uninhabited, particularly in the Barrow area. He also described a high rate of migration out of these large rural towns and into the urban centers; this is balanced, however, by migration into them and a high birth rate. I have stated (7) that these large rural towns have many characteristics of "socio-cultural disorganization"(8). One factor of this condition, as defined by Murphy, is "rapid socio-cultural change" (9) with extensive migration. While it is debatable whether or not the phrase "socio-cultural disorganization" can be applied to Barrow or Kotzebue, many of its descriptive features seem to be present.

Thus the general pattern of migration includes a flow of people, generally young adults and families, away from small villages and into larger rural towns or cities. On the other hand the small villages are maintaining their population and even growing because of the recent dramatic population explosion (10), which has produced a situation in which in the late 1960s close to 50 percent of the total Eskimo population was under the age of 14.

Differences Between Sexes in Physical Migration

We are beginning to develop a picture that points to a difference in the physical migration pattern between Eskimo men and women. Most of the evidence is not conclusive, however, and the ambiguity highlights the need for more definitive studies of this aspect of cross-cultural change in Alaska (6).

Hippler, in citing magistrates' records of the town of Barrow(6), stated that there is a "continuous migration of women out of Barrow." He saw the population dynamics as made up of the migration of families from the villages into the town and an extremely high birth rate, balanced

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Bloom is in private practice at Langdon Psychiatric Clinic, 3401 E. 42nd Ave., Anchorage, Alaska 99504, and is Associate Professor of Psychology, University of Alaska, Anchorage.

by the migration—predominantly of women—out of the town.

I reviewed 105 native Alaskan patients (7) who were referred for psychiatric evaluation and found several important differences between the men and women in the sample, one of which was a statistically significant difference between male and female migration patterns. The majority of those studied were either from large rural towns like Bethel, Barrow, or Kotzebue or from urban centers like Anchorage. A greater number of women than men had migrated to these places from the outlying villages. While the sample reflects only those people referred to a psychiatrist, it may reflect trends in the general population as well.

Despite its small sample, the recent demographic study by Milan (11) of the Arctic coast village Wainwright represents one of the few that actually measured the degree of migration out of a single village. Of those villagers who were older than 20, a greater number of women than men permanently migrated out of the village; 24 percent of the women who were older than 20 married white men and are residing in Barrow or other places. The men have either remained in the village or have demonstrated a pattern of "circular migration" (12) in which they leave the village for a period of time and then return. Milan concluded that the "Wainwright women have higher physical and social mobility than men." However, he made the assumption, which should be questioned, that these women are adequately prepared for "life elsewhere" by the years they have spent in boarding schools.

In studying the changes in population structure in several Aleutian villages, Jones (13) stated that the emigration of Aleut women who range in age from 20 to 40 years is greater than that of men. In the 1960s in "Unalaska, Atka, and Akutan, there were respectively 2.7, 1.4, and 1.2" as many female emigrants as male emigrants. This higher incidence of female emigration may be due, she speculated, to the increased possibility of these women marrying white men if they are not living in a small village.

Thus there is some evidence, however small, that Eskimo and Aleut women are migrating at a higher rate from the villages to the larger rural towns and cities and that one factor related to such migration is the possibility of marriage to nonnative men.

Differences Between Sexes in Psychopathology

In this section I will examine current evidence pointing to differential rates of psychopathology by sex in the Eskimo population. It should be understood that there have only been a few studies that have attempted to measure the true prevalence of mental disorders in specific groups of Northern peoples. Most of the other studies that I will be citing deal only indirectly with psychopathology as it exists in the general population and by sex.

Historically it is of interest to note that the early descriptions of the so-called culture-specific disorder "Pibloktoq" pointed to a definitely higher prevalence in women. For example, Brill (14), citing the work of Admiral Peary and Donald MacMillan, stated that "the disease was almost exclusively confined to the female sex." Peary, in his 25 years in the Arctic, said he had seen only one man with what might have been labeled as Pibloktoq. He further reported that of the 20 women aboard the ship *Roosevelt* eight had suffered from the disorder at various times during the voyage. Gussow (15), in a more comprehensive study of the Pibloktoq syndrome, found a greater number of cases in men than Brill did but still found a definite preponderance in women; of the 14 descriptions of the syndrome in his study, ten were of women and four were of men. There is speculation in both papers regarding the possible dynamic implications of the sexual differences of Pibloktoq sufferers.

Murphy and Leighton (16) described a general similarity between Pibloktoq in the central and eastern Arctic and what was called "amurakh" in the Siberian Arctic. Referring to an article written in 1914 about Siberian Eskimos, they cite this syndrome as predominantly affecting women.

Because of the small number of cases and the lack of recent descriptions, these accounts of culture-specific disorders may be little more than historical curiosities at the present time. However, the preponderance of cases affecting women may provide clues to some of the underlying factors in Eskimo culture that influence the woman's role.

More recent attempts at epidemiologic work have been meager and carried out only in small villages in northern and western Alaska. I am referring to the work of Chance, Hughes, and Murphy. Each used different methods to measure the signs of emotional disorder. Other authors have touched on epidemiologic considerations but only tangentially.

Chance and associates (17–20), in studying the process of cultural changes in the northern Alaska village of Kaktovik, used a modified version of the Cornell Medical Index (CMI) to measure the rates of emotional disturbance in the village population and found that the women had significantly higher scores than the men, indicating greater emotional disturbance. In one paper (17) Chance and Forster compared the scores of the Eskimo men and women with results they obtained using the CMI in various settings in New York City; they found that Kaktovik men as a group most closely resembled a random sample of New York men, while the Kaktovik women resembled a group of women either hospitalized with a diagnosis of neurosis or being treated in psychiatric outpatient facilities.

Hughes (21) studied the process of cultural transition in the village of "Sivokak" on St. Lawrence Island during the year 1955–1956. As part of the overall project, which was an attempt to study changes in the village between 1940 and 1955, Murphy and associates, using a modified version of the Health Opinion Survey, undertook a small epidemiologic survey of the village population (16, 22, 23). They found that 26 percent of the adult population had psychoneurotic symptoms and that almost two times as many women had these as men. Further, in a group ranging in age from 21 to 40 twice as many women as men had these symptoms to such a de-

gree that they were considered psychiatric cases.

In one study (7), I also found several areas of differences between women and men in the group studied. The sample primarily reflected people living in large rural towns. In addition to having different migration patterns, a greater number of women were referred for psychiatric attention (63 percent women as opposed to 39 percent men). Generally the women were younger, had less stable occupations, and were involved in more crises at the time of referral. They presented a different diagnostic pattern than the men, the women having more diagnoses of neurosis and character disorder and the men having more psychosis.

Within the confines of the limited research data available it seems possible that in certain circumstances Eskimo women demonstrate higher rates of psychopathology than Eskimo men. The two epidemiological studies cited (that by Murphy and Leighton [16] and that by Chance [19]) were done in small villages. Such studies have not been undertaken in the large rural towns or cities so that comparisons of rates of psychopathology and diagnostic patterns are only matters of speculation at this time.

DISCUSSION

In this paper I have pointed out that:

1. There has been an unparalleled population explosion among the peoples of the North within the past 20 years.
2. There is a general redistribution of young adults away from the smaller villages and into larger rural towns and urban centers. The population of the smaller villages is predominantly made up of dependent children.
3. Within this population redistribution, women more than men seem to be migrating at a higher rate away from the small villages and into rural towns and more urban environments.
4. Eskimo women seem to have higher rates of mental disorder, as measured in the population of the two small villages cited here.

Of these four points the first two are generally acknowledged to be true. The second two highlight a difference by sex in both physical migration and psychopathology. These points suggest two questions: 1) If these data reflect an accurate picture, what factors might be involved in producing these phenomena in Eskimo women? and 2) Is there a relationship between psychopathology and physical migration?

One possible formulation of the data would be that there is evidence that the differences in psychopathology described may reflect an inherent bias in Eskimo culture that places more stress and conflict on women than on men. Parker (24), in an attempt to correlate Eskimo psychopathology (in particular, hysterical behavior) with personality development, stated that the "woman's role carried with it more disabilities and less prestige than that of men"—that the female role carried with it relatively great psychological deprivation.

Lubart (25), working in the MacKenzie Delta area of Canada, carried these points a great deal farther, feeling that because of the pressures of cross-cultural change certain underlying negative factors in traditional Eskimo society are now coming to the surface. He described the following features of traditional Eskimo society as constituting the underlying "foci of tension": "1) male dominance, inflation of the male ego and depreciation of the female; 2) female resentment of the male and of the female role; [and] 3) impounding of hostile and competitive impulses" (25). With outside influences and new opportunities for change, these underlying problem areas surface and may threaten to dominate Eskimo culture. The area of impounding hostile impulses, recently described by Briggs (26), has especially important implications in that resolving conflict on an open basis may be difficult to accomplish. This inability to deal openly with hostility may constitute another important stimulus for migration.

Lubart (27) stated that the "female's rejection of her old role has become a major factor in the potential breakdown of Eskimo society." This has to be taken one step farther in that it seems that the woman who is rejecting old roles still carries with her part of the negative self-image that was important in the psychological integrity of the traditional Eskimo culture. The higher rates of psychopathology observed in the two studies described may be related to these descriptions of traditional Eskimo society.

With these views of Eskimo society in mind the stage may now be set for the reasons behind migration. Using Brody's description (12), dissatisfaction with the "donor culture" would lead to an increased desire for migration. We are here postulating that the Eskimo has an internal desire for change. This seems to be complemented by the importance of the Eskimo woman in the sexual economics of the North, where nonnative men often migrate or where they are stationed away from their own women. The "receptor culture" in the North thus needs women, and the desire for migration may be brought to reality with the Eskimo woman serving as the sexual object for the non-Eskimo man. These unions between native women and nonnative men are often based on almost movie-like romanticism and I have observed that they often end in separation, depression, and suicide attempts. These latter clinical events are most often associated with abuse of alcohol and usually occur in the larger rural towns and cities. Thus the women who are suffering from confused identity in their rejection of former roles fail in achieving a new sense of identity in the larger villages and cities.

It is interesting to note that the state and federal agencies whose "mission" it is to work with Alaskan Indians and Eskimos often encourage migration by their policies, be they in relation to health care, education, or employment. It is only in retrospect that some of the unplanned negative consequences of these policies come to light. One of my contentions is that a more subtle awareness of the traditional culture might mitigate these negative consequences. This requires a translation of cultural awareness into public policy—a difficult task if we look

at past experience with programs.

This brings us to the last point—the migration process itself. Fried (28) viewed migration as a crisis, calling it a "crisis of transition." As with any other crisis it carries implications for subsequent strengthening of character or development of psychopathology. An important determinant here is the receptivity of the new environment to the migrant. When an Eskimo moves from a small village to a rural town or city, significant changes occur. He moves from a place where his own people are the majority group to an environment where the resident population of outsiders is in control of the major institutions and where prejudice and stereotyping is often the rule. In short, the new environments do not welcome the Eskimo migrant, and the results of this often contribute to the development of psychopathology.

CONCLUSIONS

In light of the material presented in this paper we may postulate that:

1. Eskimo women in traditional Eskimo culture occupy a position of lower status than men. In the current period of cross-cultural conflict this is expressed in terms of their greater psychological conflict, with possibly higher rates of psychopathology.
2. Dissatisfaction with the traditional or "donor" culture, along with increasing contact with outside culture, leads to desire for change.
3. Due to increased opportunities for migration, especially as sexual objects, Eskimo women leave the villages at higher rates than do Eskimo men.
4. The crisis of migration itself, often coupled with failure of the interpersonal relationship that led to it, cause greatly heightened conflict and, theoretically, increased and more severe psychopathology.
5. These factors lead to severe problems of adjustment within the environment of the larger rural towns and urban centers.
6. The reciprocal effects on men would be expected to be severe.

The model suggested here must be tested. Urban studies are urgently needed for confirmation or rebuttal, and one hopes they will ultimately influence programs.

Hostility and Depression Associated with Suicide Attempts

BY MYRNA WEISSMAN, M.S.W., KAREN FOX, AND GERALD L. KLERMAN, M.D.

Hostility and depression are important factors associated with suicide attempts. Efforts to determine their respective importance, however, have been hindered because they are correlated to some extent with each other and with age and sex. The authors compared 29 acutely depressed women and 29 matched suicide attempters. Manifest hostility emerged as an important distinguishing characteristic of the suicide attempters, who had pervasive and overtly hostile relationships, a poor long-term work history, antisocial behavior, and were demanding and hostile during psychiatric interview. This contrasted with the depressives, who were compliant at interview. The theoretical and clinical implications of these findings are discussed.

THERE IS CONSIDERABLE OVERLAP in the social and personal characteristics of persons who make suicide attempts and persons who are clinically depressed. Suicide attempters are usually depressed (1, 2), and depressed patients are often suicidal (3). Difficulty in regulating and expressing hostility is another characteristic common to depressives and to suicide attempters. Those who attempt suicide, as contrasted with those who complete it, tend to be young, single, or divorced women with problematic and hostile interpersonal relations (4–6), characteristics similar to those of overtly hostile depressives, who also tend to be young women (7, 8).

Because of the similarities in age and sex between depressives and suicide attempters, it has been difficult to separate the relative contribution that hostility and depression each has made in suicide attempts. The need to separate these four variables—age, sex, depressive mood, and hostility—in studies of suicide was highlighted by the findings of a recent study of depressed patients, some of whom subsequently made suicide attempts (9). A depressed cohort was followed up ten months after the index episode, and those depressed patients who made suicidal attempts were compared retrospectively with depressives who did not make suicidal attempts. Important and potentially predictive differences between the two groups relating to the expression of hostility were found. However, highly significant differences in age and sex between the groups that may have confounded the findings were also found.

The current study controlled for the possible confounding differences between depressives and suicide attempters. Two groups of patients who were similar in degree of clinical depression, age, sex, race, and social class but who differed in having made a recent suicidal attempt were compared in an attempt to answer the following question: Is the overt expression of hostility in association with depression an independent factor that is predictive of a suicide attempt not subsumed by correlations with age or sex?

METHOD [1]

The Sample

The research sample consisted of 58 subjects who were divided into two groups, 29 depressives and 29 suicide attempters matched for sex, age, social class, race, and marital status. These 58 subjects were selected from two

This study was part of the Utilization Review and Evaluation Project, Yale University, New Haven, Conn.

At the time this work was done the authors were all with the Department of Psychiatry, Yale University School of Medicine, and its Depression Research Unit, Connecticut Mental Health Center, 100 Park St., New Haven, Conn. 06511, where Ms. Weissman is Assistant Professor in Psychiatry and Co-Director and Ms. Fox is Assistant in Research. Currently, Dr. Klerman is Professor of Psychiatry, Harvard Medical School; Superintendent, Erich Lindemann Mental Health Center; and Clinical Director, Psychiatry Service, Massachusetts General Hospital, Boston, Mass.

This work was supported by contract HSM-42-69-60 from the Health Services and Mental Health Administration and by Public Health Service grants MH-13738, MH-15650, and MH-17728 from the National Institute of Mental Health.

The authors wish to thank Alberto DiMascio, Ph.D., for his comments on this paper.

[1] This section has been abbreviated here; more detail is available from Ms. Weissman on request.

larger groups: 1) 150 acutely depressed women (the depressives) who had come for the treatment of depression but had not made a suicide attempt, and 2) 62 patients (the attempters) who came for treatment following a suicidal attempt.

The depressives (N = 150) were participants in a collaborative outpatient research study on the treatment of depression that was conducted in two facilities (Connecticut Mental Health Center and Boston State Hospital). On admission to the study, psychiatrists judged them at interview as having had an acute depressive episode of at least moderate severity, using a scale based on verbal report, behavior during the interview, and secondary symptoms of depression (10). The symptoms were of at least two weeks' duration and included as main features: depressed feelings, sadness, guilt, feelings of worthlessness, tendency to cry, weight loss, or sleep disturbance. Patients with such disorders as schizophrenia or addiction were excluded.

The suicide attempters (N = 62) were patients who had attempted suicide within the previous three days and who had come to the Yale-New Haven Hospital emergency room. A suicide attempt was defined as any intentionally self-inflicted injury (including by ingestion) unless strong evidence existed that there was not even a partial or ambiguous self-destructive intent. Lack of intent was not assumed simply on the basis of the patient's denial, absence of serious risk to life, or manipulative elements. Patients were identified as suicide attempters by the psychiatrist at the time of interview. A more detailed description of the suicide attempters and the characteristics of the attempts has been reported elsewhere (5).

Because the depressive group included only women aged 26–60, male suicide attempters and those younger than age 25 were excluded from the research sample. The remaining 29 suicide attempters were then matched with 29 depressives as to age, social class, race, and marital status. A table of random numbers was used to select matches when more than one possible match existed.

Assessments

Extensive sociodemographic, historical, and clinical information was gathered for the total sample. All raters received training in the use of the assessment instruments. Clinical depression and its symptoms were assessed by a psychiatrist at the initial interview, using the shortened form of the Clinical Interview for Depression, which is a modification of the Hamilton Rating Scale for Depression (11), and the Raskin Three-Area Scale for Depression (10). A research assistant who was not involved with the patients' treatment assessed hostility and related interpersonal functioning on two separate instruments: 1) the Social Adjustment Scale (SAS)—a modification of the Structured and Scaled Interview to Assess Maladjustment (SSIAM) (12), and 2) the Recent Life Events (RLE)—a modification of the Holmes and Rahe scale—which recorded interpersonal stress in the preceding six months (13). Administration, item content, reliability, and validity of the SAS and the RLE have been described elsewhere (13, 14).

Marital status			n.s.
Currently married	13	12	
Not currently married	16	17	

*Based on Hollingshead's Two-Factor Index of Social Position (15).

Data Analysis

Differences between the two matched groups of 29 suicide attempters and 29 depressives were examined. Means were examined for continuous variables, and cross tabulations were examined for categorical variables. T tests or chi-square analysis with Yates correction, where appropriate, were used to test whether the two groups came from the same population. Two-tailed tests were used and the .05 level of significance was accepted.

RESULTS

As shown in table 1, there were no significant differences between the depressives and the suicide attempters in sex, age, social class, race, or marital status. These findings were expected in that the two groups had been matched on these variables.

Even though the subjects were not matched a priori on clinical status, data analyses revealed no differences in degree of clinical depression. As shown in table 2, both groups were rated as moderately depressed on the two clinical evaluation ratings—the Clinical Interview for Depression (derived from the Hamilton Scale) and the Raskin Three-Area Scale for Depression.

Seventeen variables assessed family background and premorbid psychiatric and social history in both patient groups. Four of the variables significantly differentiated

TABLE 2
Degree of Clinical Depression in Depressives and Suicide Attempters

Means of Assessment	Range of Scores	Attempters (N=29)	Depressives (N=29)	Level of Significance
Clinical Interview for Depression	1–7	3.03 ± 1.08	3.07 ± 0.50	n.s.
Raskin Depression Scale	3–15	8.92 ± 3.26	8.97 ± 1.40	n.s.

the suicide attempters from the depressives. Compared with the depressives, the suicide attempters had made a greater number of previous suicide attempts, had a more frequent history of drug use and criminal convictions, and had a more impaired total work record (table 3). The history of drug use was of a minor degree in both groups since major drug abuse excluded depressives from the original study.

Premorbid history and family background, as recorded in the social history, were strikingly similar in both groups. About 40 percent of both groups had been permanently separated as children from their fathers, either by death or by desertion. Fifty percent had close family members who had received psychiatric treatment; about 25 percent had close family members who had been treated for a depressive illness.

Individual clinical symptoms were assessed during psychiatric interview, when a psychiatrist made ratings of 13 individual symptoms using the Clinical Interview for Depression. As described previously, both groups were moderately depressed. The individual assessments provided an opportunity to examine the characteristics of specific depressive symptoms rather than only the broader diagnostic categories (see table 3). Attempters, as compared with depressives, had exhibited significantly less depressed appearance, less pessimism and hopelessness, and less impairment in their work performance during the previous week. While the attempters tended to have a generally poor work record that did not change much in the week prior to the suicide attempts, the depressives, on the other hand, had a stable work history but had an acute change in their work performance in the week prior to coming for treatment.

Suicide attempters were significantly more overtly hostile and demanding during the interview. Evidence pointing to hostile interpersonal relations outside the clinical interview was obtained from nine assessments. The SAS included five assessments of interpersonal friction over the past two months, and RLE included four assessments of an increase in arguments over the past six months. Six of the nine assessments significantly differentiated suicide attempters from depressives. The suicide attempters had significantly more overt interpersonal friction and a significantly greater number of increased arguments both with family members (extended family, distant relatives, and spouse) and with friends and dates. These difficulties were reported as occurring during the past two months and as extending to the previous six months (table 3) and were consistent with observations of increased hostility during the interview.

DISCUSSION

Depression and hostility are widely regarded as important characteristics of persons who make suicide attempts. Attempts to investigate their respective roles in the genesis of suicidal behavior, however, have been hindered because these two factors are not only correlated to some extent with each other, but also with such other characteristics as age and sex.

In this study we were able to delineate the relative independence of hostility and depression in suicide attempters by controlling for the potentially confounding effects of age and sex. Moreover, both depressives and suicide attempters were found to be moderately depressed to the same degree. Hostility, which was overtly expressed in the clinical interview and in interpersonal relations, still emerged as an important characteristic of suicide attempters.

The suicide attempters' interpersonal difficulties were both recent and of longer term, extending to a number of relationships within and outside of the family. The suicide attempters appeared at psychiatric interview with less depressed appearance and pessimism but with considerable overt hostility, irritability, and complaining behavior. Other differences between depressives and suicide attempters were few but consistent. The suicide attempters were more likely to have a history of excessive drug use, legal difficulties, and an impaired long-term work record.

There are limitations to this study that should be noted: Information was collected from the patient and was not confirmed by the patient's significant others; raters were not blind to the subjects' conditions. However, the consistency of the findings and their similarity with those of other studies suggest that these findings have implications for theory and clinical practice.

The Scope of Hostility in the Lives of Suicide Attempters

Hostility can be simultaneously viewed as a personality characteristic and as a quality of interpersonal relations. From both viewpoints the suicide attempters have difficulties in the regulation and the expression of overtly hostile feelings.

These findings are identical to the recent report by Paykel and Dienelt (9), who followed 189 depressed patients for ten months after the index episode. Of the original cohort, 12 patients attempted and one patient committed suicide. These 13 patients were compared retrospectively with the 176 depressives who did not make an attempt. The attempters were found to have a history of excessive drug use, previous suicide attempts, and increased overt hostility that was present both at the initial interview and at follow-up. Moreover, an excess of overtly directed hostility in depressed patients, especially at the time of psychiatric interview, was an important in-

dication of future suicidal behavior. Findings of Paykel and Dienelt, as noted before, may have been confounded by the fact that the group of suicide attempters was significantly younger than the nonattempters, were exclusively white, and while including only one male attempter, was compared with a depressed group of which 24 percent were men. However, when these sociodemographic differences were controlled in the current study, the results were still similar.

Other empirical studies and clinical reports have also commented on the presence of hostility in suicide attempters. Birtchnell and Alarcon (16) compared 91 suicide attempters with depressed outpatients and found that the attempters were younger and equally depressed. The suicide attempt usually followed an acute conflict with another significant person with whom the attempter had an intensely hostile and ambivalent relationship. Philip (17) examined personality characteristics of suicide attempters, neurotics, and normals. While he found no unique suicidal personality, he described suicide attempters as being poorly integrated and as having considerably more generalized hostility and interpersonal frictions. Vinoda (18) also compared suicide attempters to other psychiatric patients and found that the attempters scored very high on general hostility. Maris (19) found an association between sexual deviancy, drug abuse, marital problems, and suicide attempts. He set forth an intriguing hypothesis regarding cause and effect which stated that sexual deviancy and drug abuse were ways of coping that, if stigmatized, led to suicide attempts.

Clinical reports have discussed ways of predicting to what degree depressed patients are at risk for suicide. Many clinicians have discussed the relationship between hostility and suicide attempts. Lesse (20) described an increase in rage, defiance, discontent, nagging, and complaining as being of prime predictive importance in impending suicide attempts. When these behaviors were observed in a depressed patient who was under stress, impulsive, and had shown antisocial activities, the potential for a suicide attempt was especially high. The eruption of rage in a depressed patient has been noted by others (21–23) to indicate potential risk. Rosenbaum and Richman (24) observed that suicide attempters generate considerable hostility among those around them. An overwhelming degree of anger was expressed by relatives toward the attempters as compared with the feelings of relatives of other groups of patients.

Psychodynamics of Hostility and Depression

These findings have implications for the continuing exploration of the psychodynamic relationships between hostility and depression. The classical view, derived from early formulations by Abraham (25) and by Freud (26), has emphasized the mechanism of "hostility turned against the self" in the psychogenesis of depression. Carried to its logical conclusion, this formulation does not afford depression an independent role either as an affective state or as a clinical syndrome. Recent ego-psychology formulations derived from Bibring's far-reaching theory have provided for the independence of depression as a primary affect and for the pathogenesis of clinical depression as separate from the vicissitudes of aggressive drive (27, 28). Empirical studies by a number of investigators have supported Bibring's view (29–31).

TABLE 3
Comparison of Depressed Patients and Suicide Attempters

Variables Characterizing Attempters Compared with Depressives	Level of Significance
Social History	
Previous suicide attempts	$p<.001$
Excessive drug use	$p<.05$
Criminal convictions	$p<.05$
Impaired total employment history	$p<.05$
Clinical Symptoms	
Less depressed mood	$p<.01$
Less pessimism and hopelessness	$p<.01$
Less impaired recent work and interests	$p<.01$
More hostility at interview	$p<.05$
Interpersonal Difficulties	
Family	
More friction with relatives	$p<.05$
Increased arguments in family	$p<.05$
Increased arguments with relatives	$p<.05$
Increased arguments with spouse	$p<.01$
Friends	
More friction with friends	$p<.05$
Increased arguments with dates	$p<.05$

The findings from this study provide further empirical support for Bibring's theory. Hostility and depression were independent. Even when the level of depression was equivalent, the suicidal attempter had a greater number of manifestations of hostility during the clinical interview and in interpersonal relations than the nonattempter. A complete test of the alternative psychodynamic hypothesis is not possible since the psychodynamic formulations involve unconscious as well as conscious hostility, and the current study employed research methods that assessed only manifest hostility. Nevertheless, the findings are most compatible with a theory that regards hostility and depression each as a primary affect, rather than with one that regards depression merely as the transformation of hostility via retroflexion onto the self.

Assessment of Hostility

The pattern of overt hostility observed in the suicide attempters at the time of interview may be particularly important. Previous research has noted a differential relationship between hostility and depression depending on the intimacy of the interpersonal relationship (32). Acutely depressed women, when compared with normals, expressed considerably more overt friction in most interpersonal relations; this friction was greater with close members of the nuclear family than with friends, neighbors, or distant relatives. At psychiatric interview, however, the depressed woman was not hostile but was cooperative, compliant, and docile. It was suspected that the discrepancy between the depressed woman's behavior at interview and at home accounted for discrepancies in the

literature about hostility in depressed patients.

In contrast, the suicide attempters were uncooperative, complaining, and hostile when interviewed. Overt hostility at interview is one of the more important distinguishing features of the attempters. Clinicians may feel that a depressed patient who becomes overtly hostile, especially to staff, is improving. Our results suggest a contrary interpretation. Angry, complaining, hostile behavior to strangers and to staff in a depressed patient may be indicative that he is at risk for suicide attempt.

Treatment and Prevention

The hostility in the suicide attempters may have distracted the clinician from noting that they were also moderately depressed, as depressed in fact as the patients who had already been found suitable for pharmacologic and psychotherapeutic treatment. Silver and associates (1) have noted a lack of controlled studies that measure the effect of antidepressant therapy on the wish to die and on subsequent completed suicide. The Boston-New Haven Collaborative Depression Project (33) found a marked drop in suicidal tendencies in depressed patients who were given antidepressants during the first four weeks of treatment. Most of the improvement occurred in the first week of treatment, and few suicide attempts occurred during further treatment. It is possible that successful treatment of the depression may have reduced the suicidal risk.

Given the amount of hostility displayed at interview, the suicide attempter is often unlikely to be diagnosed and treated as depressed, and even if he is diagnosed as depressed, he may be difficult to engage in treatment. Suicide attempters alienate staff, family, and friends. In treatment their hostile behavior may lead to early discharge or dropout. We found them to be an especially uncooperative group for follow-up studies. Although all but one patient in this study was referred for psychiatric treatment, 25 percent of the suicide attempters were not receiving psychiatric treatment one week after the suicidal episode, and by two weeks this figure had risen to 43 percent, indicating failure to become engaged in treatment. Attrition from an eight-month outpatient treatment program in the depressed sample was infrequent, occurring in less than 15 percent of the sample (33). The tendency of the suicide attempters to have a less overt depressed appearance can be misleading. Given their high potential for successful suicide and their tendency to underrepresent their depression and to alienate staff and family, maximum efforts to treat and follow the suicide attempters should be made.

CONCLUSIONS

The suicide attempter is usually depressed, hostile, and immersed in a network of interpersonal relations that are frustrating and maladaptive. Their personality resources seem to be inadequate to cope with the burden of both depressed and hostile feelings, and as their defenses fail, symptom formation spills over into acting out. The suicide attempt may thus be viewed as the result of a failure to achieve more mature forms of psychodynamic defense and as a form of acting out. The suicide attempt serves multiple functions, including as a means of communicating the attempter's despair and helplessness and, one hopes, mobilizing persons around the attempter, including mental health professionals, to come to his assistance.

Hopelessness, Depression, and Attempted Suicide

BY KENNETH MINKOFF, M.D., ERIC BERGMAN, AARON T. BECK, M.D., AND ROY BECK

The authors have identified a component of the syndrome of depression—the cognitive element of negative expectations—as a stronger indicator of suicidal intent than depression itself. This not only suggests a solution to the puzzling question of why there is a relationship between depression and suicide, but also indicates that approaches specifically designated to alleviate hopelessness may be successful in preventing suicide.

THE QUESTION of what motivates an individual to attempt or to commit suicide has puzzled the lay public and professionals alike. Laymen are prone to state empathically that such an individual "was at the end of his rope," "could see no other way out"—was, in a word, hopeless.

On the basis of clinical observation of suicidal persons, several investigators have reached similar conclusions. Beck (1), in an intensive study of 50 depressed suicidal patients in psychotherapy, noted, "Suicidal preoccupations seemed . . . related to the patient's conceptualization of his situation as untenable or hopeless. . . . The suicidal patients generally stated that they regarded suicide as the only possible solution for their desperate or hopeless situations." These patients were later able to regard their hopelessness as cognitive distortions or as derived from erroneous or unrealistic premises. Farber (2) observed, "It is when the life outlook is of despairing hopelessness that suicide occurs." Similar observations have been made by Kobler and Stotland (3).

The paucity of systematic research to test and explore these clinical observations of the relationship between hopelessness and suicide is striking. One explanation is the entrenched belief of many clinical investigators that hopelessness is a diffuse feeling state and therefore too vague and unquantifiable to be systematically investigated. Stotland's review of the literature on hopelessness (4), arguing eloquently against this belief, proposed that hopelessness can be readily objectified by defining it as a system of cognitive schemas whose common denominator is negative expectations about the future. Thus, a pessimistic or hopeless individual expects or believes that nothing will turn out right for him, nothing he does will succeed, his important goals are unattainable, and his worst problems will never be solved. This definition of hopelessness (or pessimism) as a set of negative expectations about the future is used in this paper.

Another possible explanation for the sparse research on the relationship of hopelessness to suicide is that the main thrust of clinical research in this area has explored the link between depression and suicide. However, although the relationship of depression and depressive illness to attempted and completed suicide has been fairly well established by a variety of studies (5–10), there are few data to suggest the nature of this relationship. At least three possibilities should be considered. One possibility is that suicidal behaviors are an intrinsic part of depression, just as fever is an intrinsic part of pneumonia

Based on a paper read at a New Research session at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors were all with the Departments of Psychiatry at the University of Pennsylvania and the Philadelphia General Hospital, where Dr. Minkoff was formerly and Mr. Bergman is now a student, Dr. Beck is Professor, and Mr. Beck is Research Associate; Dr. Minkoff will shortly begin residency training in psychiatry at the University of California, San Diego, Calif. Address reprint requests to Dr. Beck, Fourth Floor, Stouffer Building, Philadelphia General Hospital, 34th St. and Curie Ave., Philadelphia, Pa. 19104.

This work was supported by Public Health Service grant MH-15989 from the National Institute of Mental Health.

TABLE 1
Demographic Characteristics of 68 Suicide Attempters

Category	White	Black	Puerto Rican
Male			
Under 35	14	11	1
Over 35	8	3	0
Female			
Under 35	11	15	1
Over 35	3	1	0

(although it is not always present). Another possibility is that the statistical association between depression and suicide is merely an artifact resulting from a joint attachment to a third variable, such as age, to which each is directly statistically related. Finally, there is the possibility that depression and suicide are related because each has an underlying *causal* factor in common.

Menninger (11), one of the major exponents of the third hypothesis, utilized Freud's classical theory of depression to argue that both depression and suicide were expressions of introverted unconscious hostility. This thesis has not been supported by experimental work (7). Newer theoretical constructs of depression by Beck (7, 12, 13), Bibring (14), Gaylin (15), and others have de-emphasized the role of retroflected rage and have focused on what Beck (7) has termed "the Cognitive Triad of Depression," i.e., "negative attitudes of the depressed individual toward himself, the outside world, and his future" (12). This triad is viewed as a key underlying the other phenomena of depression.

Several empirical studies support the statistical relationship between hopelessness and suicide. In a systematic investigation of suicide notes, Bjerg (16) reported that in 81 percent of the notes the writer regarded himself "as having a desire . . . which could not, cannot, or will not be fulfilled." Farnham-Diggory (17) reported that suicidal patients showed a significantly constricted subjective view of the future, compared with the nonsuicidal patients. Ganzler (18) compared six groups (ten men and ten women in each group) on various social and interpersonal perceptions: one group in life crisis who were suicidal; one group in life crisis who were not suicidal; one group of noncrisis, nonsuicidal psychiatric outpatients; and three groups of normal subjects. He found that, although all three psychiatric groups described their current life situations in negative terms, *only the suicidal group rated the future negatively*, in particular by anticipation (and fear) of social isolation in the future.

In a factor analysis of the Beck Depression Inventory (19), Pichot and Lempérière (20) isolated a factor with high loadings for only two items: hopelessness (.40) and suicide (.34). Cropley and Weckowicz (21) reported an identical factor with even higher loadings on hopelessness (.53) and suicidal wishes (.57). Beck's analysis of the intercorrelations of individual items on the Depression Inventory showed that suicidal wishes correlated more highly with hopelessness than with any other item (7).

In the present study, using quantitative measures of hopelessness, depression, and the seriousness of intent of a suicide attempt, we attempted to investigate the relationship of hopelessness and suicide by testing the following hypotheses:

1. A significant correlation exists between negative expectancies (hopelessness) and seriousness of intent of suicide attempters.
2. Seriousness of intent of suicidal attempts is more closely related to hopelessness than to the syndrome of depression in general.

METHOD

The sample consisted of 68 consecutive suicide attempters admitted to Philadelphia General Hospital over a period of six months. There were 37 men and 31 women (two of whom were pregnant); 36 were white, 30 were black, and two were of Puerto Rican descent. The range of ages was from 14 to 63, and the mean age was 29.4 years. The demographic characteristics of the sample are presented in table 1.

With regard to social variables in the sample, 38 were single, 19 separated, six divorced, one widowed, and only four married. There were 28 Catholics, 28 Protestants, six Jews, and six with no religious affiliation. The mean educational level was 10.47 years of schooling.

Each patient in the sample was assigned a psychiatric diagnosis in accordance with the *Diagnostic and Statistical Manual of Mental Disorders*, second edition (22). The diagnosis was related to the *acute* reason for the current admission and was based on a combination of evaluation by the house staff (for those patients admitted to psychiatric wards) and clinical evaluation by our research staff. The distribution of acute psychiatric diagnoses in the sample was as follows: 45 (66.2 percent) had a depressive disorder (neurotic or psychotic) and 23 (33.8 percent) were diagnosed as schizophrenic. Ten patients were admitted to medical wards and the remainder (88.5 percent) to the psychiatric inpatient service.

Forty-seven patients attempted suicide by ingestion of some dangerous substance; 44 of these (65 percent of the total) ingested coma-producing drugs. Nineteen (28 percent) had used cutting or piercing instruments and the rest had used a variety of methods including hanging, jumping, and drowning; six (nine percent) had used more than one method.

The decision to include a patient in the sample was based primarily on the determination that he actually was a suicide attempter, as opposed to a threatener or ideator, to a self-mutilator with no intention of killing himself, or to a patient who had accidentally inflicted self-injury or unintentionally taken an overdose of a drug. For this determination, we used the criteria of Silver and his co-workers (10): 1) a patient was included if he stated that he had deliberately harmed himself in order to terminate his life; 2) a patient was included regard-

less of how slight or how great his injury was; and 3) a patient was *not* included if he had threatened or considered suicide but stopped short of carrying it out (such as standing on a bridge but not jumping).

Each patient in the study was seen within 48 hours of admission to the hospital on two separate occasions by members of our research staff. In one interview, conducted by an experienced clinician, the patient was evaluated clinically and a comprehensive history, including the circumstances and state of mind at the time of the suicide attempt, was taken. In addition, data regarding medical, social, and family history were collected. The second interview, conducted by a psychological technician, elicited a large amount of detailed personal information from the patient, including in particular demographic data and patterns of alcohol and drug use. In this interview, the patient was given the Beck Depression Inventory (BDI) (7) and the Generalized Expectancies Scale (GES) (23).

The major findings of the present study are based on the results of the BDI, GES, and Suicidal Intent Scale for each patient. The BDI was used as a means of measuring the intensity of depression (irrespective of primary diagnosis); it includes cognitive, affective, motivational, and vegetative elements of depression. The possible range of scores is 0–63 (7). The GES consists of 20 statements about the future, which the patient marks as true or false. The score ranges from 0, representing no hopelessness, to 20, representing maximum hopelessness. There is considerable evidence of the concurrent and construct validity of this scale: it correlates well with other scales intended to measure future time perspective; the scores correlate well with clinical ratings of hopelessness; and the scores correlate with ratings of depression and reflect changes in depression (23).

The Suicidal Intent Scale, developed by our research unit (24), is a 15-item scale that evaluates the seriousness of the patient's psychological intent by assessing the circumstances surrounding the attempt and the patient's post-attempt description of his intentions and expectations during the attempt. The scale does not rely on the physical damage resulting from the attempt or on any demographic or historical data. The range of scores is from 0 to 30. The score on the Suicidal Intent Scale is determined by the clinical interviewer on the basis of data elicited in the interview. The first section of the scale (items 1–9), "Circumstances related to suicide attempt," deals with factual aspects of the attempt (e.g., timing, planning, suicide note). The informants are the patient and another reliable person. The second section (items 10–15), "Self-report," is used to record retrospectively the patient's thoughts and feelings at the time of the attempt.

Thirty-one of the patients in our sample were compared for interrater reliability on the Suicidal Intent Scale by two independent raters, and the correlation was found to be .95. The correlation between the "Circumstances" subscale (items 1–9) and the "Self-report" subscale (items 10–15) was .43 ($p < .01$) on a sample of 68 patients.

The construct validity of the scale is supported by the finding of Silver and his associates (10) of a significant positive correlation between depression and intent in 45 suicide attempters and by the finding of Beck and associates (24) that the mean intent score on the "Circumstances" subscale was significantly higher in a group of 31 successful attempters than in a group of 49 unsuccessful attempters.

It should be noted that the BDI and GES were administered and scored in a separate interview by an interviewer other than the clinician who conducted the clinical interview, completed the Suicidal Intent Scale, and made the diagnosis.

RESULTS

The mean score on the BDI for the full sample was 21.93, with a standard deviation of 13.2; the mean GES score was 7.87, with a standard deviation of 6.1; and the mean Suicidal Intent Scale score was 12.87, with a standard deviation of 6.2.

A correlation matrix was calculated using the following variables: age, Suicidal Intent Scale score (Intent), GES score, and BDI score. It was found that age showed no significant correlation with any of the other variables.

As expected, the BDI and GES scores showed a highly significant positive correlation ($r = .68$). The positive correlation of Intent and GES ($r = .47$) was significant at the .001 level, while the correlation of BDI and Intent ($r = .26$) was significant only at the .05 level. Using Hotelling's test of the difference between two dependent correlation coefficients, we found that the correlation between Intent and GES was significantly higher than that between Intent and BDI ($p < .001$). Further computations revealed that the partial correlation of Intent with GES (holding BDI constant) was .41 ($p < .001$), while the partial correlation of Intent with BDI (holding GES constant) was −.09 (nonsignificant).

Additional analyses were conducted in order to determine whether scores on the two subscales, "Circumstances" (items 1–9) and "Self-report" (items 10–15), were consistent with the findings of the whole Suicidal Intent Scale. This was particularly important since only the first subscale had been validated in comparisons with completed suicides (24). We found that the analyses of the subscales conformed to the findings reported above. The correlation of "Circumstances" with the BDI was $r = .13$ (nonsignificant) and with the GES was $r = .31$ ($p < .01$); the significance of difference between these was $p < .10$. The correlation of "Self-report" with the BDI was $r = .30$ ($p < .01$) and with the GES was $r = .64$ ($p < .001$); the difference between these was significant ($p < .001$).

The sample was divided into three groups of roughly equal size according to the BDI score, and a one-way analysis of the variance of the mean Intent scores for each group was performed. The analysis revealed a positive nonlinear variation of Intent with BDI, but this was not significant ($p < .10$). A similar analysis was per-

formed on the variance of Intent with GES. The analysis showed a positive linear variation that was statistically significant ($p < .01$).

The data were further analyzed by dividing the sample into two roughly equal groups according to both GES (0–7 and 8–20) and BDI (0–19 and 20–63) scores and then comparing the mean Intent scores in the four paired groups: low hopelessness-low depression (N = 26, mean Intent score = 10.27); low hopelessness-high depression (N = 9, mean score = 9.11); high hopelessness-low depression (N = 8, mean score = 16.38); and high hopelessness-high depression (N = 25, mean score = 15.80).

Whether the BDI (depression) scores were high or low, the groups with high GES (hopelessness) scores had the higher mean Intent scores. Using t tests of the differences between the mean Intent scores in the various groups, the following results were obtained: 1) between high GES-low BDI and low GES-high BDI, $t = 2.88$ ($p < .025$); 2) between high GES-low BDI and low GES-low BDI, $t = 1.93$ ($p < .10$); and 3) between high GES-high BDI and low GES-high BDI, $t = 3.24$ ($p < .005$). The results indicate that intent varies with hopelessness regardless of whether depression is high or low; however, when depression is high, the difference is very significant, but when depression is low the difference does not quite attain significance.

The data were then analyzed for each of the two diagnostic groups in the sample: schizophrenia (N = 23) and depressive disorder (N = 45). Though each patient fell into one of these groups of *acute* diagnosis, some patients also had additional chronic problems, such as alcoholism, drug abuse, or a character disorder. In the group of schizophrenics, mean Intent = 13.46, mean BDI = 24.17, and mean GES = 8.12. In the group of depressives, mean Intent = 12.55, mean BDI = 21.34, and mean GES = 7.66. The differences in means between the diagnostic groups and between each group and the total sample were not significant.

The difference between the two diagnostic groups was striking. In the depressive group, with schizophrenics eliminated, the correlation between BDI and Intent became highly significant ($r = .44$, $p < .005$). However, the correlation between GES and Intent was even more highly significant ($r = .64$. $p < .001$); using Hotelling's test, we found that the difference between the correlation coefficients for GES-Intent and BDI-Intent was as significant ($p < .001$) for depressives alone as it was for the whole sample.

In the schizophrenic group, the correlation of BDI and Intent ($r = -.07$) was negative and insignificant. The correlation of GES and Intent *was* positive ($r = .27$), but it was not significant, perhaps because of the small number. There was a difference between the correlation coefficients that was certainly suggestive of a trend, but this was not significant either.

DISCUSSION

The findings supported the hypotheses. We found a highly significant positive correlation between the level of hopelessness (as measured by the Generalized Expectancies Scale) and the seriousness of suicidal intent (as measured by the Suicidal Intent Scale) over the total sample. This significance was retained in the nonschizophrenic diagnostic group, but the correlation was positive though not significant in the schizophrenic diagnostic group. We also found a significant positive correlation between depression and intent in the total sample, especially in the depressed group. The latter result replicates the findings of Silver and his co-workers (10) in a similar study; 90 percent of their sample consisted of depressed patients and they also found a significant positive correlation between depression and intent.

Further, hopelessness showed a closer relationship to intent than did depression. In the total sample, this was indicated by the significantly higher value for GES versus Intent ($r = .47$) than for BDI versus Intent ($r = .26$), by the significant partial correlation of Intent with GES, by the highly significant positive variance of Intent with GES, and by the significantly higher mean Intent scores in the groups with high hopelessness scores than in those with low hopelessness scores, whatever the level of depression.

It is interesting to note that schizophrenics, despite their small number, showed a positive (though nonsignificant) correlation between intent and hopelessness and a noticeably (though not significantly) closer relationship of hopelessness to intent than of depression to intent. This indicates that, although the research is oriented more toward nonschizophrenics, the hypotheses have been supported to some extent regardless of diagnostic group.

We have thus identified one factor in the syndrome of depression—the cognitive factor of negative evaluation of the future (pessimism or hopelessness)—as apparently being more closely related to the seriousness of intent than to depression itself. In examining this finding, we must consider whether the data might be biased by the fact that the sample consisted only of suicide attempters admitted to the hospital. We must also question whether there might be a bias due to the fact that Philadelphia General Hospital tends to serve a population of lower socioeconomic background. There is no a priori reason to assume that, even if such biases do exist, they exert a significant influence on the results. However, at present, the generalizability of the findings is limited to suicide attempters of low socioeconomic status who are admitted to a general hospital.

It is also important to observe that, although we have suggested a relationship between hopelessness and suicidal intent, this does not prove that hopelessness *causes* suicidal behavior. In fact, the correlation between the measures of hopelessness and intent accounts for only 22 percent of the variance. Thus, although the results support the clinical and theoretical hypothesis that hopelessness is the common causal factor linking depression and suicide, further work is necessary to show how hopelessness leads to suicidal behavior.

CONCLUSIONS

Studies by other workers have already identified depression as a danger sign of possible suicide and have indicated that the danger increases as the degree of depression increases. The present study suggests that hopelessness is another danger sign, perhaps more sensitive than depression, of the seriousness of suicidal intent. This finding suggests that, if we focus on reducing a patient's hopelessness, we may be able to alleviate suicidal crises more effectively than in the past. This might, for example, be accomplished by a psychotherapeutic approach in which negatively distorted expectations for the future are corrected. On the other hand, if the patient's hopelessness is based on objective factors, appropriate social intervention may provide the necessary environmental changes to alleviate the reality situation.

Videotape Confrontation After Attempted Suicide

BY H.L.P. RESNIK, M.D., W.T. DAVISON, M.D., DEAN SCHUYLER, M.D., AND HM3 PETER CHRISTOPHER, USN

The authors report a new treatment approach for suicide attempters in which the patient's condition, the measures taken to save his life, and the reactions of his family are recorded on videotape when the patient is brought to the emergency room. After psychotherapy has begun, the patient views the videotape. This method challenges the patient's denial of despair and suicidal intent by confronting him with the consequences of his suicidal behavior. The authors point out the potential usefulness of videotape confrontation for a broad spectrum of self-destructive patients.

> Oh wad some power the giftie gie us to see oursels as others see us.
>
> —ROBERT BURNS, *To a Louse* (1786)

SUICIDE RESEARCH has shed increasing light on the prediction, identification, and assessment of the suicidal patient. There has been less achieved, however, in the area of treatment. Suicide ranks as the 11th leading cause of death in the United States. It can be estimated that 25,000 people will die a self-inflicted death and that 250,000 others will make a suicide attempt this year (1, 2). Unfortunately, they will be treated with a variety of rather conventional psychotherapeutic approaches, none of which has been adapted specifically for the suicidal person.

Treating the seriously suicidal patient poses significant problems for the clinician. Nowhere else in his practice is the psychiatrist faced with a "life-or-death" situation; the suicidal crisis is the most frequent psychiatric emergency physicians are called upon to treat. A sense of urgency is present that may influence the choice of a therapeutic approach. The clinician is often confronted with his own feelings about death and self-destruction when treating a suicidal patient. The explicit need to involve the spouse (3), the immediate family (4) or members of the extended family (5), and significant others may be contrary to his usual therapeutic stance. Nevertheless, we believe that many serious suicide attempts occur in sociopsychologic contexts that require active and precise information.

Once committed to the treatment of a suicidal patient, further problems may arise for the therapist. Suicidal ideas may be fleeting. Especially during the period after an attempt, motivation for self-exploration may be lacking. Suicidal intent, or indeed the suicidal behavior itself, may be denied, distorted, minimized, or rationalized. Rapid discharge from a hospital emergency room (frequently to the very circumstances that precipitated the behavior) with subsequent discontinuation of therapeutic contact is not unusual (6). Resistance or denial by the family as well as by the patient may frustrate attempts to encourage meaningful therapeutic involvement (6, 7). Finally, the nature of the attempt as an appeal may often be answered, albeit in a temporizing way. Thus the new equilibrium that is achieved rejects clinical intervention that might examine and disturb its tenuous nature.

When the clinician does have a motivated patient, other problems still remain. How can he approach the suicidal patient in a way that will maximize the chance for a positive outcome? Psychodynamic individual psychotherapy requires time, intellect, a philosophical commitment, and an evolving relationship for success. However, denial or distortion of the suicidal behavior may be an impediment to treatment. Group therapy does afford the opportunity for early and multiple confrontations of the patient with the direct consequences of his suicidal ideas or behavior, but this technique is limited since frequently neither the attempter, the other patients, nor the therapist knows anything specific about the suicide attempt—and all tend to minimize it and pass it by. Furthermore, Frederick and Farberow (8) have noted that group therapy with suicidal patients can impose a great emotional drain on the therapist, with a limited return for the patient.

The value of group therapy may be in maintaining large numbers of chronically suicidal patients in a peer-supported context. Group therapy is a technique therapists can use to motivate denying patients immediately after an attempt. Goldberg and Mudd (3) have explored marriage counseling and note that the patient's frequent suicidal communications to the spouse may militate against involving the spouse in therapy. "Relearning" approaches have been suggested by Frederick and Res-

Dr. Resnik is Chief, Mental Health Emergencies Section, National Institute of Mental Health, 5600 Fishers Lane, Rockville, Md. 20852; he is also Consultant at the Naval Hospital, National Naval Medical Center, Bethesda, Md. Dr. Davison was formerly Staff Psychiatrist, Naval Hospital; he is now Instructor in Psychiatry, Georgetown University Medical School, Washington, D.C. nik (9), but such a technique requires cooperation from the patient and his family; moreover, punishing, extinguishing, or learning to avoid such a response as suicidal behavior does not always decrease or remove the stimulus.

Resnik and others, in a number of papers (9, 10) and editorials (11, 12), have pointed out the need for new and innovative treatment techniques to overcome the clinical problems outlined above, as well as the greater use of those which do exist. This paper will describe the adaptation of videotape confrontation for use with patients who have made a suicide attempt and who are exposed to emergency medical care and its sequelae. We believe the procedure offers a potentially fruitful approach to the suicidal patient and his family. We call the technique the Self-Exposure Experience (SEE).

Recently, Berger brought together in one volume (7) the multiplicity of techniques and clinical indications for the use of videotape, but its use with suicide attempts was not included. Cornelison and Tausig (13) have employed a videotape taken at the time of psychiatric illness as a means of enhancing self-understanding in psychotherapy. Moore and associates (14) showed that initial psychiatric interviews recorded on videotape and replayed for the patient enhance therapeutic progress. Danet (15) has demonstrated that seeing oneself on videotape may challenge the defense of denial. He has stated that for some patients a visual image carries more weight than "innumerable verbal confrontations." Berger has carried the concept further. His recently reported split-image technique (16) appears to be a modified Rorschach, utilizing the patient's associations to his own highly personalized perceptions of the images. Alger and Hogan (17) have integrated the use of videotape into their practice of conjoint marital therapy.

All of this might be paraphrased as follows: A picture of the treatment of a suicide attempt may be worth a thousand words in therapy afterward.

METHOD

Each patient brought to the emergency room of the Naval Hospital (located at the National Naval Medical Center, Bethesda, Md.) following a suicide attempt is evaluated by a psychiatrist after the appropriate emergency medical treatment has been provided. When the patient first arrives, our on-call videotape team is alerted; they obtain consent for taping from the patient (if he is capable) or a relative. The patient's condition, the life-saving measures taken, and his interaction with hospital personnel are recorded. Special efforts are made to videotape the reaction of the family if they are present. Closeups are employed to capture the patient's facial expression (confusion, disorientation, agitation, or lethargy) as well as those of his family (concern or indifference).

After emergency care is rendered, the patient is admitted to the hospital service dictated by his physical condition. If he has gone to intensive care or general surgery, he is transferred to the psychiatric service when he is ambulatory and alert to his surroundings. Often, almost a week may have elapsed between the emergency room treatment and the transfer. The patient's memory of the event may be understandably impaired. Once admitted to psychiatry, the patient attends sessions in individual and group psychotherapy and participates in the milieu program with other (nonsuicidal) patients. After two individual therapy sessions, which allow him an opportunity to discuss his situation, he is brought to a SEE videotape session, in which his emergency room behavior is viewed.

In the SEE session, the patient sits in an upholstered chair in a quiet viewing room with subdued lighting. His anxiety level is measured by administering the State-Trait Anxiety Inventory (STAI) (18). Electrodes are applied to permit continuous measurement of his galvanic skin response (GSR) (19). The baseline response is monitored for two minutes, using a neutral stimulus (a picture of an armchair on the videotape monitor), and the patient is then shown a ten-minute segment of the emergency room videotape. The "State" scale of the STAI is readministered as a measure of anxiety after the patient has seen the tape.

SEE sessions follow each two individual therapy hours until there is a decrease in the amplitude and frequency of GSR responses and in the STAI score and the treatment team feels that the videotape sessions have "served their purpose." The goal is to actively engage the patient in psychotherapy by the time the SEE is discontinued.

CASE REPORTS

The following case reports illustrate the courses of two patients treated in this program.

Case 1. A 21-year-old married secretary walked into the emergency room and announced that she had ingested the contents of a bottle of 100 aspirin tablets. Her speech was slurred and her eyes were swollen. Intravenous puncture, gastric lavage, and the psychiatric interview were videotaped. She revealed that she had dropped out of college the year before to share the burden of financial support with her husband. She wept as she described how she had disappointed her father. Her mother had made many suicidal gestures when the patient was younger. Earlier on the day of admission, the patient had been arrested for shoplifting, only one week after her husband had left her.

The patient was admitted to the medical service for 24 hours and then was transferred to psychiatry. On the psychiatric service she said that she felt fine and wished to leave the hospital. When she persisted in her desire to leave against medical advice, she was shown her videotape. Obviously shaken by the SEE, she stalked out of the viewing room into her doctor's office. With anger, she accused him of sadistically exposing her to the pain of seeing her videotape. She was able to trace her fury to an early memory of her mother: "That's just the way my mother looked after she attempted suicide." She remembered the anger, frustration, and despair that she had experienced as a child after her mother's frequent suicide attempts. She recognized that she was copying the behavior of a woman whose selfishness and heartlessness had angered her.

Although she initially denied suicidal intention, she sub-

sequently became aware of her ambivalence over living with her present marital discord. She gradually accepted responsibility for her own self-injurious behavior and willingly remained in the hospital to work out a less destructive way of dealing with her conflict. After four weeks of psychotherapy and four SEE sessions, the treatment progressed from the immediate precipitating situations to other issues. The number of GSR arousal patterns had decreased from 11 in the first session to one in the fourth session. The physiological indicator of a decrease in anxiety was consonant with a clinical decrease in denial of her suicidal intent and its prodromata. (This patient was not evaluated on the STAI scales since the schedules had not been received.)

The SEE seemed to confront this patient with the fact that she was emulating her mother, something she could not bring herself to accept. She might well have come to that conclusion in a more conventional therapy regimen, but certainly not as vividly and not as soon. The unconscious resistance that was inhibiting her accessibility for treatment was clearly and incisively uncovered so that the patient could work with it immediately.

Case 2. A 22-year-old male dental technician who had been in psychotherapy for two years had ingested ten secobarbital capsules and slashed both wrists one week after his psychiatrist left for vacation. He was brought to the emergency room by his roommate. The painful cleansing of his wounds and a short interview were recorded on videotape. The patient revealed that he wanted to die because he felt that no one cared for him. His mother and father were divorced and emotionally distant. He had lived with his father since the age of 12. He felt that his friends were using him.

He was admitted to the psychiatric service and viewed the SEE as described in our protocol. Before viewing the videotape, he was quite verbal in psychotherapy sessions, but quite intellectual about his difficulties in sustaining a meaningful human relationship and his despair at "being abandoned" during his psychiatrist's vacation. After the first viewing session, he was silent in treatment for the first time. Then he said, "I can't deny it, there I was. I really tried to kill myself." He poured out feelings of despair and related dreams of his fears and wishes for death. After the second SEE he angrily accused his therapist of conducting an investigation of him. "You know a lot more about me than you are telling. You're just waiting for me to say that I've had trouble with women so that you can say you knew it." The patient related his difficulty in dealing with women to the mistrust he had for his mother, who had abandoned him at age 12. After the third SEE he said, "First I blamed the staff and the doctors for what I felt but it's not you, it's me."

In the last SEE session, the decrease in the STAI score and concurrent decrease in GSR complexes were consonant with the decrease in the patient's denial and projection. He had established a firm working relationship with his therapist and had ventilated his anger clearly; the SEE was discontinued. For this patient, the videotape confrontation seemed to cut through the defense of intellectualization and to allow him to feel his desperation and the deep feelings of abandonment that preceded his self-destructive behavior.

DISCUSSION

In the two cases presented, denial of despair and suicidal intent were challenged by visually confronting the patient with the consequences of his suicidal behavior. This encouraged the patient to express feelings related to the suicidal act. In each case, relevant material was stimulated that helped to engage the patient in the therapeutic alliance.

It is of interest that, following videotaped confrontations, both patients vented hostility upon the therapist as their predominant initial defensive posture. This situation was manageable in therapy and could be interpreted as stimulating further interaction on the feeling level. In time, both patients were able to assume responsibility for their suicidal behavior and begin to understand some of its antecedents. In ensuing sessions, they could relate their self-destructive impulses to significant experiences both present and past. Issues related to the suicidal act remained prominent in therapy for four to six weeks in both cases. We feel that this is much longer than in the usual (non-SEE) treatment for suicide attempts. One of our hypotheses is that recidivism is correlated with the paucity of time spent in therapy considering the real events surrounding the actual suicide attempt, with a detailed medical evaluation of the risk to life. The shorter the time this is considered and the sooner the search for psychodynamic variables begins, the more likely another attempt will occur. The more the medical discussion is continued, detailed, and reported, the less likely there will be a repeat attempt. Repeatedly viewing the medical consequences prior to regular office visits, as in SEE sessions, may serve as a negative reinforcer of the suicidal behavior (10).

Serber (20) has reported a behavioral technique called "shame aversion therapy," in which social confrontation of the performance of a deviant act by the use of film or videotape frequently produces aversion to the deviant act (in this case, exhibitionism).

In seeking to understand these outcomes, there are additional factors inherent in the treatment of the patients that merit consideration. Perhaps both patients evidenced only token denial, which might have succumbed to verbal confrontation alone. The attention associated with a unique treatment modality may have an important effect on the patient's self-esteem. The therapist, too, may have put out a special effort with these patients because of the intellectual stimulation of a new technique. A follow-up study with appropriate control groups is currently planned to assess the impact of videotape confrontation and alternative factors in the short-term treatment of the suicide attempter. The technique also holds promise for those families who reinforce the patient's denial, who refuse to become involved, and who insist on the accidental nature of the attempt (21, 22). We are currently evaluating the use of SEE sessions with such families.

Recently, we presented videotapes of two adolescents (12) who rationalized and denied their behavior until they saw the tapes of their parents nakedly distraught. The youngsters could not maintain their feelings that they were unloved, feelings that had led to their suicide attempts.

The potential usefulness of videotape confrontations is limited only by the accessibility of equipment (which is becoming increasingly available) and the clinician's will-

ingness to make himself available when the emergency medical care is being given. One can foresee, for example, utilizing this technique with a variety of patients engaged in self-destructive acts. The juvenile diabetic or the difficult-to-manage epileptic who is recurrently brought to the emergency room in coma can later be confronted with the results of his neglecting to take his medications. Applications have been designed for the alcoholic, but the use of tapes with the drug addict is yet to be reported. The consequences of discontinuing any life-preserving medication could be forcefully illustrated to the patient. The clinical indications of SEE sessions are relevant to a broad spectrum of self-destructive patients who have traditionally been viewed as problems in medical and psychiatric management.

Suicide and Psychiatric Education

BY WILLIAM A. KELLY, JR., S.T.M.

The author's literature survey suggests that the incidence of suicide among psychiatric residents is probably similar to that among residents in other specialties and may not be very different from that of other males in the same age group. However, the problem merits attention not only because lives are being wasted, but because psychiatrists and other physicians are in short supply and their importance to the community is considerable. The author believes that efforts to prevent physician suicide should begin in medical school, where the students should explore their inner conflicts and unsatisfying social interactions. During their residencies psychiatrists should be helped to prepare themselves to endure the irrationalities of their patients and the burden of isolation in their professional practice.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The Reverend Mr. Kelly is Associate Chaplain, Herrick Memorial Hospital, Berkeley, Calif. 94704.

This research was made possible by a grant from the A.E. Bennett Neuropsychiatric Foundation.

IN THE FALL OF 1970, at the hospital where I was then engaged in chaplaincy training, a first-year resident committed suicide by taking an overdose of drugs. His death followed by less than two weeks the suicide death of a discharged woman patient for whose care he had been responsible. A month later, in apparently quite independent circumstances, a psychiatrist associated with the staff of the same hospital killed himself. The dismay, frustration, dejection, and anger among those directly acquainted with these persons and events lasted for many months.

Not unexpectedly the questions were asked, especially with reference to the two physicians' suicides, "Why did they do it? What might we have done to prevent their deaths? What should we be doing to help other troubled colleagues?" Because another resident had committed suicide two years earlier, the additional question was asked, "Is our experience here unique, or is there a generally high incidence of suicidal behavior or emotional disorder among psychiatry residents?"

In the medical literature considerable attention has recently been given to suicide by physicians (1–4). The suicide rate for psychiatrists has been suggested to be the highest of that for all medical specialties (1, 5). While investigation and thought have been given to the emotional problems and personality changes of psychiatry residents (6, 7), mining of the literature has turned up little statistical information about the actual frequency of suicide and mental illness among these residents. In order to determine whether this was a subject meriting intensive, in-depth research, it was decided to take the first step of discovering the extent of the problem. Dr. A.E. Bennett of Berkeley, Calif., who for many years has shown an active interest in quality psychiatric care and suicide prevention (8), gave immediate encouragement and counsel to a proposal for a research project and arranged for a grant of funds.

METHOD

Our aim has been to delineate the nature and extent of the problem of suicide and psychiatric disability among residents in psychiatry. By means of a questionnaire, we sought to obtain information for the ten-year period July 1960 to June 1970. The questions covered the incidence of suicidal behavior and other acute emotional disturbance among residents in psychiatry and also inquired about how those responsible for psychiatric training programs identify, respond to, and arrange treatment for disturbed residents. Space was given for the respondents' opinions about suicide prevention and mental health care for residents.

The questionnaire was mailed to 249 psychiatric residency program directors throughout the United States, covering the one-, two-, and three-year residencies listed in the *Directory of Approved Internships and Residencies* of the American Medical Association. Since the replies represented a self-selected sample, we chose a random sample of 28 of the 249 programs to provide a check on questionnaire results. We asked members of the random sample if during the period under study any psychiatric residents had committed suicide while in training; if the answer was "yes," we asked how many.

There were 88 questionnaire replies (about 35 percent of the training programs addressed) that furnished usable figures on suicide and disability among residents. Analyzing this sample for distribution by geographical region and by size rank in 1970–1971, we concluded that we had information from a representative cross section of all residency programs in the United States. Ten of the 88, or 11.4 percent, reported resident suicides during the ten-year period.

We had only 26 replies to the letter sent to 28 programs in the random sample. Of these, 25 answered "no" to the question about suicide by a resident during the ten years. Unable to extract replies from two members of the sample, we presumed "yes" answers for them, to raise the possible suicide incidence rate. These three "yes" answers gave a ten-year rate of 10.7 percent of training programs that presumably experienced resident suicides; this was not very different from the rate of the 88-member sample. Recognizing that these figures do not meet strict standards for purposes of parametric statistical analysis, we nevertheless believe that they are sufficiently good indicators for reporting and discussion.

Tables 1 and 2 summarize the information derived from the 88 questionnaire replies. No significant differences were found among programs when they were grouped according to size or geographical location.

RESULTS

Suicide Among Physicians

Such data as the literature furnishes on suicide by psychiatrists and psychiatry residents have been reported in discussions of suicide by all physicians. In 1971 Ross (4) presented a comprehensive survey of the international literature of the past 75 years on this subject. Discussing the incidence of doctors' deaths by suicide, he stated, "While ... rates vary from country to country, everywhere suicide appears to be an extraordinarily high risk for the doctor" This view seems to prevail fairly widely in the profession. To what extent is it valid?

In May 1965, the *Journal of the American Medical Association* began to report suicides among the causes of death of physicians. Late in 1968 two groups of investigators, who had worked independently, published their analyses of the *JAMA* information on physician death by suicide. Blachly, Disher, and Roduner (1) calculated that 2.66 percent of physicians' deaths during the 110-week period of their study were by suicide. They gave a suicide rate for all physicians of 36 per 100,000 per year, ranging from a low of ten per 100,000 for pediatricians to 61 per 100,000 for psychiatrists. Blachly and associates did *not* state that the overall physician suicide rate was unusually high. Rather, they said, "It appears that although the risk of suicide is very high among some doctors, it is negligible among others.... Specialty

seems to be a highly significant variable.... The large number who commit suicide in their early twenties and thirties is impressive" (1).

Craig and Pitts (2), covering physician suicide data for the 104-week period following mid-May 1965, not only counted physician suicide deaths reported by *JAMA* but also reviewed death notices received too late for *JAMA* publication and a number of ambiguously reported deaths. Their suicide count was somewhat higher than that of Blachly and his co-workers. Craig and Pitts gave a suicide death percentage figure of 2.72 percent, with an overall crude annual suicide rate of 38.4 per 100,000. Allowing for underreporting, they estimated that "the true suicidal rate in male physicians is probably at least 2.97 percent of deaths and 42 per 100,000 per annum" (2). They adopted the important assumption that the age distribution of the U.S. physician population corresponds to that of the overall U.S. white male population over age 24, and compared their findings with those published by Dublin and Spiegelman in 1947 (9).

After statistical analysis of their data, Craig and Pitts concluded:

> The rates calculated for male physicians are not different from those of 25–30 years ago, nor do they differ from those calculated for an appropriate segment of the general population of the United States. These results stand in marked contrast to conclusions drawn by others from their assessments of suicide by U.S. physicians.... Our assumption is that this is because previous studies have not been systematic nor have all the available records been examined (2, p.767).

Their rates for the various medical specialties ranged from 7.5 per 100,000 for radiologists and 15 for pediatricians to 65 for psychiatrists and 100 for otolaryngologists. Except for the high rate for otolaryngologists (a generally older group of practitioners), Craig and Pitts were of the view that the variations by specialty "have no statistical significance and therefore probably no other meaning, unless it can be shown that the differing rates among the various specialties occur regularly until larger numbers accumulate with the same sub-group suicide rates" (2).

At this juncture, then, it cannot be said with any degree of confidence that physicians in general, and psychiatrists in particular, do in fact kill themselves more frequently than other white males in the same age range in the general population.

Craig and Pitts (2) did find a significantly high rate of suicide in female physicians; with Freeman (5) and Blachly and colleagues (1), they underscored the point that most physician suicides seem to occur at ages when there is the possibility of many remaining years of professional service (2).

Suicide by Psychiatric Residents

Craig and Pitts (2) also presented statistics for deaths by residents, grouped according to specialty. They reported 13 resident suicides out of a total population of 31,687 residents in the U.S. during the two-year period of their investigation. Four of the 13, or 31 percent of all resident suicide deaths, were of psychiatry residents, the largest percentage among the specialties. This number of cases was too small to attain statistical importance. Their conclusion was: " None of the suicided resident specialty groupings differed from the distribution of residents by specialty in the U.S." (2). For the resident population as a whole, Blachly and associates (1) calculated a suicide death rate of 15 per 100,000 per year, while Craig and Pitts give the rate as 21. The discrepancy is not significant. Blachly noted that "the rate for residents was only one-half that for interns" (1).

TABLE 1

Programs Responding to Questionnaire on Suicidal Behavior or Psychiatric Disability Among Residents: 1960–1970 (N = 249)

Item	Number of Programs	
Programs reporting suicides, suicide attempts, or other psychiatric disabilities		54
Suicides*	10	
Suicide attempts	21	
Other psychiatric disabilities	45	
Programs reporting no suicides, suicide attempts, or other psychiatric disabilities		34
Programs replying to questionnaire		88

*One program reported two suicides; nine programs reported one suicide.

Turning to our own study (summarized in table 2) from a sample of 6,285 psychiatric residents, we report 11 suicide deaths. This is a rate of about 18 per 100,000 per year, which is not statistically different from those given in the two studies mentioned earlier. What those investigators discerned for a two-year period appears to hold true also for the ten-year period considered by our study. What statisticians sometimes call the "null hypothesis"—namely, that the suicide rate for psychiatric residents is the same as for all resident physicians—has not been disproved.

The Emotional Health of the Psychiatric Resident

Ten years ago Halleck and Woods (6) described some of the emotional problems of psychiatric residents. They noted then that statistics were not available as to the number of severe psychiatric decompensations occurring in residents, but "it would be over-optimistic to assume that they did not occur"; they appealed for frank recognition, open discussion, and careful study of the resident's emotional difficulties. Quite recently Pasnau and Bayley (7) published a useful summary of the literature pertaining to the difficulties experienced by psychiatry residents and then went on to discuss personality changes taking place in the first year of training. They observed a significant increase in the level of depression during the first year's training experience of residents they studied.

In our questionnaire study, we asked psychiatric train-

TABLE 2
Residents in Psychiatry Reported To Have Shown Suicidal Behavior or Experienced Psychiatric Disability During Training, 1960–1970

Item	Number of Residents	
Total number of residents trained by 88 programs replying to questionnaire		6,285*
Suicides	11	
Suicide attempts	31	
Other psychiatric disabilities	225*	
Total suicides, suicide attempts, other disabilities		267

*Figures are estimates, as some replies were approximate answers to questions on these points.

ing directors: "For the period under study, how many trainees other than those who have shown overt suicidal behavior have experienced a mental disturbance of sufficient intensity to require special therapy or hospitalization?"

The answers provided a total of about 225 residents. The respondents usually made it clear that their replies did not cover residents who were in therapy primarily for training purposes. The figure does not include those who might have been ill and have undergone treatment without the knowledge of their training directors, or those who were disturbed but carried on their work unnoticed. The number of suicides—11—plus 31 suicide attempts and 225 other psychiatric disabilities comes to 267, which gives a psychiatric resident casualty rate of something over four percent. While this cannot be offered as a "hard" statistic, it points to the inference drawn by Holt and Luborsky (10) over a dozen years ago from their study of psychiatric resident personality patterns and selection procedures:

> Some may get the impression that psychiatric residents are a remarkably immature or neurosis-prone lot. There is every reason to believe, however, that in these respects they do not differ much from young physicians learning other specialties. . . . Our findings support the conclusion that the great bulk of competent residents (and probably of good practitioners generally) are healthy, conventionally adjusted people (10, pp. 69, 281).

Stress Factors in Residency Training

Among the factors that have been identified as contributing to the stressfulness of the psychiatric residency years are: the resident's efforts to achieve identity and competence in his specialty; a heightened awareness of his own intrapsychic conflicts; the responsibility, often assigned in the first year, for the care of seriously disturbed inpatients; discouragement at the results of outpatient psychotherapy over a limited period with an unrepresentative group of patients; and conflicting advice from supervisors or teachers (6).

Institutional patterns and events may put additional strain on the resident's inner resources. Stanton and Schwartz (11), in their study of a mental hospital, noted that conflict and low morale among staff members led to an increase in pathological excitement among patients and a widespread intramural "collective disturbance." Their dictum, "The environment may cause a symptom," merits wider acknowledgment than it has probably received. When there is organizational change, group conflict, and staff disagreement within a training program, one may expect an increase in uncertainty, anxiety, and depression among staff members, including residents. Stanton and Schwartz suggested that organizational difficulties and staff disaffection be dealt with directly, openly, and specifically.

The care of suicidal patients is itself a risk element. In a study of the impact of the suicide of hospitalized patients on their psychotherapists, Kahne (12) found that in a certain hospital:

> Among 22 resident psychiatrists having from one to four years training, 14 percent had already had a patient commit suicide. . . . [It may be that] residents are being asked to assume responsibilities that they may not yet be equipped to handle (12, p. 36).

The 88 answers to our questionnaire survey indicated that over a ten-year period, 54 training programs (more than 60 percent of the sample) had the experience of one or more residents going through a serious emotional crisis during his training years (see table 1). Ten programs reported resident suicide deaths; 21 acknowledged suicide attempts by residents. In nine programs one resident had committed suicide, while in one program, two were reported to have killed themselves.

The survey answers showed a wide variety of attitudes and arrangements among the training programs with regard to the emotional needs of residents. One training director wrote: "There is a primary focus on the emotional stability of the resident as a key factor in his effectiveness as a therapist." In contrast, another director said: "Mental health care for psychiatrists and psychiatric trainees is not a function of the training program. . . . If one has to study the trainee population and seek out those who are unstable and then push them into therapy, they should not be in the profession." It is our subjective impression that half of the respondents showed a positive interest in assisting residents in personal growth and emotional maturation as part of their professional training.

Fifty-four training directors emphasized the importance of careful selection procedures in identifying latent pathology in applicants for residency positions. Only two of these mentioned any reliance upon psychological testing, although tests are now available, especially the Minnesota Multiphasic Personality Inventory, which can measure personality characteristics associated with suicide potential (13). The personal interview is the screening device most often relied upon.

For many years some programs have required residents to undergo personal analysis or psychotherapy. One respondent described the practice of giving each first-year resident 36 hours of "personality assessment" with an analyst; another offered 50 hours of voluntary individual therapy without cost to the resident (14). Thir-

teen respondents referred to their use of group dynamics and sensitivity training with uniformly positive evaluation. Four others described voluntary group therapy arrangements, with a large majority of residents electing to take part. Sadock and Kaplan (15) described in detail one such program at the Metropolitan Hospital Center in New York City. Sherman and Hildreth (16) reported on a group process seminar that increased the residents' awareness of and effectiveness in dealing with some of their own destructive ways of participating in groups. In one large residency program, new residents are regularly advised that suicidal thoughts may occur to them and require treatment but that this would not entail their expulsion from the program.

CONCLUSIONS

The findings of our study indicate that the incidence of suicidal behavior among psychiatry residents in the United States is probably not different from that of other residents. Possibly it is not different from that of males in the same age range in the general population. Psychiatric resident suicide and behavioral disorder is part of the larger problem of emotional or mental illness or suicide by physicians in general. The problem merits attention not so much because physicians are clearly in an inordinately high-risk profession but because, as Craig and Pitts have put it, "physicians are in short supply, their importance to their communities is considerable, and the loss of even one physician by suicide in mid-career is an event which should be prevented" (2). Neither physicians nor residents in emotional crisis are likely to reach out to, or be reached by, the suicide prevention and crisis intervention services that have been developed in many communities across the country.

Knowledge is available to those in psychiatric education regarding how to recognize psychological difficulties in applicants and in residents and regarding how to deal promptly and constructively with symptoms of disturbance (17–19) so that the chances of premature disablement or suicide by a resident are lessened and he can be assisted toward greater effectiveness as a person and as a practitioner. Putting it more bluntly, we know how to reduce the number of breakdowns and suicides by residents below the present level if we wish to do so. Measures toward this end that commend themselves include: 1) psychological testing and psychiatric interviewing at the time of selection; 2) sensitive individual supervision; 3) early, explicit discussion of suicidal thoughts and other stress reactions that the resident may be expected to experience; 4) periodic evaluation of emotional development during training; 5) participation in an intensive personal group; 6) selective assignment to stressful responsibilities; 7) recognition of crisis situations, e.g., a patient suicide or organizational disorder; 8) prompt referral for treatment, preferably without financial burden to the resident; and 9) anticipatory exploration of the heavy demands and relative isolation of private practice.

Perhaps the most pertinent question of all is: What can be done during the years of residency to prepare the psychiatrist to cope more readily with personal depletion and distress throughout the years following formal training, when he will be fully engrossed in his practice, carrying the burden of his patients' fears, angers, and self-loathings and separated from close personal contact with understanding colleagues? Following the deaths mentioned at the beginning of this paper, a psychiatrist in private practice wrote of his own experience of the personal cost of helping others: "Medical school and psychiatric training didn't teach us to take care of ourselves, to be sensitive to our own needs and give them priority equally with those of our patients."

The helper needs to learn to help himself and to ask help from others. Simon (20) urged that doctors should have an annual "emotional health check-up" comparable to the regular physical examination they recommend to their patients. Explicit attention in residency training to the young psychiatrist's emotional problems and resources for self-care may encourage him to overcome tendencies toward self-isolation and denial of personal difficulties and needs. But, as Halleck and Woods (6) and Ross (4) have emphasized, efforts to prevent physician suicide must begin in medical school. As early as possible the doctor-in-training should learn how to explore his own inner conflicts and unsatisfying social interactions and to work with others in effecting constructive personal change. Either in medical school or residency a place should be given in the curriculum for introducing the related disciplines of suicidology and crisis intervention, with the expectation that recognition and treatment of acute stress reactions, depressive illness, and suicidal behavior will be of both professional and personal benefit to the resident.

An important issue, one that appears to be still moot in psychiatric circles, concerns the appropriateness and method of active intervention when a colleague shows signs of serious depression or expresses—directly or indirectly—a self-destructive bent. Ross has urged that:

> To make prevention more than a pious hope, students and faculty must be more keenly alert and become more effective interventionists. . . . If physicians exercise enlightened compassion with regard to mental illness in their fellow physicians, they will not be reluctant to intervene when necessary, without becoming overprotective or callously rejecting him (4, pp. 192, 195).

For the profession, then, the question remains: What are the responsibilities of friendship and partnership to the emotionally disturbed physician colleague?

Suicide and Newspapers: A Replicated Study

BY SOL BLUMENTHAL, PH.D., AND LAWRENCE BERGNER, M.D.

To determine the importance of imitation in the act of suicide, the authors replicated a study by Motto that dealt with the relationship of suicide rates to the cessation of newspaper publication caused by a strike. Using the population of New York City during a partial newspaper strike, they compared the rates of suicide during this period with the rates during identical periods of three preceding years and two subsequent years. They found that while the overall suicide rate was not significantly reduced, the suicide rate of young women under age 35 was lower.

THE IMPORTANCE OF IMITATIVE behavior in the act of suicide has been considered since ancient times. Durkheim (1) suggested that if this imitative factor were significant, suicide should vary with the importance newspapers have in public opinion. He acknowledged a lack of "established facts" but reached the conclusion that the existence of such a relationship is unlikely. Motto (2) has recently reported evidence of imitative behavior in suicide related to the availability of newspapers in Detroit. Previously, Motto had failed to detect a relationship between the suicide rate and the cessation of newspaper publication in seven large cities in the United States (3).

During the Detroit newspaper strike lasting from November 17, 1967, to August 10, 1968, there was a reduction in the number of suicides among women; the number of suicides among men was not significantly different. The existence of a relationship between newspaper reporting and suicide would have important implications for understanding the dynamics of suicide and its possible prevention. It was therefore decided to attempt to replicate the Detroit study in New York City.

The problem was approached by using a population as its own control; its suicide rate during a period when newspaper publication had ceased was compared with its mean rate of suicide for the identical period in the preceding three years. In Motto's study of Detroit data a four-year mean was used.

New York City has had two major newspaper strikes, one from December 8, 1962, to March 31, 1963, and the other from April 24, 1966, to September 11, 1966. The earlier strike was included in one of Motto's studies (3) in which no differences were found.

It is with the latter 140-day strike, "the longest labor shut-down in American newspaper history" (4, p. 47), that this study is concerned. While the duration of this strike was shorter than the 268-day strike in Detroit, it

At the time this work was done the authors were both with the New York City Department of Health, Health Services Administration, 125 Worth St., New York, N.Y. 10013, where Dr. Blumenthal is Principal Research Scientist (Behavioral Sciences), Office of the Deputy Administrator for Research, and Dr. Bergner was Assistant Commissioner for Research and Professional Training. Currently Dr. Bergner is Commissioner of Health, Department of Public Health, Seattle, Wash.

was felt that the number of suicides in New York City is large enough that random and sampling variations would be kept to a minimum.

Unlike the complete suspension of all newspaper publication in Detroit, this strike in New York City was not complete but affected half of the six newspapers that were then in operation. In that the situation in New York was not truly comparable to the one in Detroit our attention was turned to the effects of this long and partial cessation of newspaper publication on the suicide rate. The three newspapers affected by the strike provided about 30 percent of the total daily circulation in New York City and 20 percent of the weekend circulation. The three operating newspapers did not increase their circulation to the extent that they acquired the entire readership or circulation of the other three newspapers. In fact, it seems that there was a decline in total newspaper circulation after the strike had been concluded (5, 6). The sharp reduction in readership during the newspaper strike and its possible effect on the suicide rate is the focus of this study.

METHOD

The age and sex of those persons who committed suicide during the newspaper strike of April 24, 1966, to September 11, 1966, as well as the method they used, were determined; the suicide rates of age- and sex-specific groups were calculated and restated as suicide rates per 100,000 per year. The same data were obtained and the rates similarly determined for the identical period for each of the preceding three years, the mean of those years serving as the expected rate of suicide for the strike year. These data also served to determine whether a discernable trend might alter the expected figure for the strike year. The same procedure was then followed for the two years subsequent to the strike year for further comparison.

The total population of New York City did not change to any appreciable extent during the period 1963–1968. The U.S. Census reported the population of New York City to be 7,781,984 in 1960 and 7,895,563 in 1970. However, a comparison of age- and sex-specific groups in 1960 and 1970 showed considerable change so that it was necessary to perform linear interpolation between the 1960 and 1970 census for age-sex groups. These interpolated figures were used in computing rates.

RESULTS

The number and rates of suicide during the newspaper strike and during the corresponding three-year periods and subsequent two-year periods are summarized in table 1. The number of suicides as well as the rate are included to indicate the sample size from which our inferences are drawn. In those younger than 15, the small number of suicides (eight during the six years examined) did not permit meaningful comparison; this age group is thus not represented as a separate column in table 1 although it is included in the "all-ages" category.

The overall rate during the strike (11.7) was not significantly lower than the mean rate for the preceding three years. It fit well into the overall declining trend of the three preceding years, and the percentage of the observed change from the previous year was within the range of prior fluctuation. Similar findings were noted when men and women were examined separately.

The rates for specific age groups showed no consistent change during the strike. A comparison of combined age- and sex-specific groups revealed no consistent reduction in the number of either male or female suicides in any age group. The suicide rate during the strike fell within the range of prior fluctuations for three same-age groups of men and two same-age groups of women. These sex-age groups, which were outside the range of prior fluctuations, were almost evenly divided between new highs and new lows.

Motto employed the Wilcoxon Matched-Pairs Signed-Rank Test, a nonparametric test that takes into account both the direction and magnitude of observed changes. If the male and female populations of New York City are considered separately and if each age group is used to form matching pairs (three-year mean rate and rate during the strike), applying this nonparametric test to the New York City data would indicate that the changes in the male and female suicide rates during the strike are not statistically significant.

Examination of data for the two years following the strike indicates that the overall suicide rates continued to decline and were less than both the three-year mean rate and the strike period rate. Similarly the rates for men as well as the rates for women declined during the subsequent years and were less than the three-year mean rate and the strike period rate. Comparison of age-specific groups revealed no consistent changes from the strike year, with the rate of three age groups increasing and that of three decreasing in subsequent years. Combined age- and sex-specific group comparison revealed no consistent pattern either for men or for women.

It should be noted that for women in the younger age groups, 15–24 years and 25–34 years, the suicide rates during the strike period were the lowest in the six years studied, fell below the prior range of fluctuation, and were followed by an increased rate in the subsequent year. The subsequent increase may be important in view of the overall downward trend in suicide rates. It was pointed out in the Detroit study that a reduction in the suicide rates of women was observed "especially in the age group under 35." This finding is of interest because it occurred both with the complete and the partial cessation of newspaper publication.

DISCUSSION

In this study we did not find any relationship between the suicide rate and the partial cessation of newspaper publication in New York City from April 24–September

TABLE 1
Number and Rate** of Suicides by Age, Sex, and Year*

Year and Sex	15–24		25–34		35–44		45–54		55–64		65 and Older		All Ages***

*Number of suicides from April 24 to Sept. 11 in each year examined.
**Rate is corrected for suicides per 100,000 per year.
***Includes those younger than age 15, a total of eight during the six years examined.
†Rate is lower than in 1963–1965.
††Rate is higher than in 1963–1965.

11, 1966. The findings are consistent with Motto's study of seven large cities (3) but contrast with his study of complete cessation of newspaper publication in Detroit (2). This difference in findings may be attributed to the lack of complete cessation of publication in New York City.

Within a radius of 75 miles of the Empire State Building there are 12 television stations in the city's core, 19 TV stations on the fringes of the area, 72 AM radio stations, 71 FM radio stations, 54 daily newspapers, 285 weekly or biweekly newspapers, 38 foreign-language or ethnic newspapers, and 28 magazines with a circulation in excess of 100,000 in the metropolitan area (7).

Although one may speculate that daily newspaper reports and photographs have a unique quality and emotional impact, they are certainly not as dominant in reporting suicide as they have been in the past.

Like the Detroit study, our study took place during a gradual decline in suicide rates. Such a decline was occurring while there were major shifts in the composition of the New York City population. In 1966, whites, who make up a majority of the city's population, were for the first time outnumbered by blacks and Puerto Ricans in the public-school population. Comparison of the populations in the 1960 and 1970 censes showed a decline in those aged 35–64 years. This shift to a younger population with a different ethnic composition could account for the general decline in suicide rate. While the nonwhite population was also increasing in Detroit, the age- and sex-specific population in that city are reported to have shown little change. If there were sizable population shifts in Detroit (census data were not available to Motto at the time of his study), then one might expect differences in the computed rates.

The possibility that newspaper reports could be responsible for triggering potential suicide victims had been posed as early as 1845 by A. Brigham (3, p. 252) and has been speculated on ever since (8). While it may be possible to cite examples where triggering could have taken place, it has not been established that newspapers were directly responsible. If suicide is contagious (9), there must be many different sources of contagion. Friedman (10) and others (8, 11) have pleaded for the suppression of sensational newspaper reporting in order to reduce the occurrence of suicide. Even if the triggering theory were correct, in the current social and communications climate would not other triggering mechanisms also come into play?

Weighing the doubtful and very slight possible advantages of reducing the number of suicides against the price of suppressing all judicious publicity, Durkheim (1) believed that imitation (of a suicide) does not occur often enough to affect the suicide rate of a given society. In fact, there is hardly anything that any individual can do that will affect the collective life. "Thanks to the almost unanimous and generally ancient predominance of collective states, they are far too resistant to be offset by an individual innovation." This view is supported by the "40

percent increase in suicides in Los Angeles during the month of the suicide of Marilyn Monroe in August 1962 without significant change in the yearly suicide rate" (3).

A more current theme, and one that criticizes Durkheim's position, is that the mass media are responsible for inculcating in suggestible individuals a wide spectrum of antisocial thoughts with the consequence of antisocial behavior (suicide, crime, drug addiction, etc.)(11).

We must conclude that there is no firm and consistent evidence that suicide prevention will be enhanced by influencing the newspapers to reduce the emotion-laden reporting of suicides.

Suicide and the Right to Die

AT LEAST ONE recent court case has upheld a patient's right to freedom from unwanted intervention in the process of dying. Medical societies across the country are publicly supporting carefully considered decisions to limit intervention in terminal illness. Excesses of therapeutic zeal, bred of a burgeoning life-support technology, are giving way to a more careful consideration of the patient's humanity. At the same time, euthanasia receives little public support. The deliberate induction of death is foreign to the spirit of medicine. But we are once again becoming aware of the mortally ill individual's right to die with dignity.

Physicians know full well they cannot prevent death. They can only postpone it. Where death is imminent—and every clinician knows that judgment is fugitive at times—the questions are when and how, not whether. Suicide, or the threat of it, raises the question of *whether*, in the sense that death is not otherwise near. Symposia, panel discussions, and debates have been held on the question of the individual's right to suicide. But the assertion of such a "right" leaves out of consideration what is known about those who have taken their lives. So-called "rational" suicide is a rarity. Only a few persons who commit suicide are suffering from a terminal illness (and may perhaps be excluded from the discussion that follows). The descriptive facts are that most persons who commit suicide are suffering from clinically recognizable psychiatric illnesses often carrying an excellent prognosis; that the majority have sought help from physicians for their symptoms; and that few have received the indicated treatment. To say that this person is exercising a right is to mock him in his frustration at failing to find the understanding and the technical skill he sought.

To be sure, there are those who condemn any effort to interfere with an individual's behavior against his wishes. But their grounds are philosophical, not clinical, and foreign to our concerns as physicians. Others, in the hope of de-stigmatizing suicide, would establish "thanatoria" to facilitate, regulate, and sanitize the act. This idea seems to be the intellectual toy of frustrated would-be suicide preventers. There is much to be frustrated about. Our ability to predict suicide is still crude. Our ability to prevent suicide is at best unproven. The loss of federal support for research in these vital areas coincides with an unprecedented rise in suicide among the young. But suicide is not a topic on which to take the position: "If you can't beat them, join them!"

From our knowledge of the natural history of the psychiatric disorders underlying the suicidal urge, we can confidently predict recovery from that urge in the great majority of cases, when other symptoms of depression lift. The desire to terminate one's life is usually transient. The "right' to suicide is a "right" desired only temporarily.

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

Every physician should feel the obligation to support the desire for life, which will return even in a patient who cannot believe that such a change can occur. To cooperate in the patient's hopelessness violates an important responsibility of the physician.

GEORGE E. MURPHY, M.D.

Dr. Murphy is Professor of Psychiatry, School of Medicine, Washington University, St. Louis, Mo.

Kudos

ALL EDITORS OF SCIENTIFIC JOURNALS have two baskets on their desks: one for bouquets, the other for brickbats. Unfortunately the latter is usually full, while the one for bouquets is sparsely populated. Therefore when a number of approving letters arrive at his desk, an editor is tempted to make Brownie points by publishing them. Until this time we have refrained from this reaction, but now a series of notes about our new format has led us to abstract and publish some of them herewith. First a telegram:

"Congratulations on your new dress. January issue more impressive than ever. Best wishes and bouquets to all."

Then letters:

"I think the new format of the *Journal* is a vast improvement and extremely good."

"I'm moved to write this letter after picking up the current issue of *The American Journal of Psychiatry*. It is now an even more impressive-looking journal and a delight to read in its spacious, wide-column format. Thank you for changing the *Journal* in this way. Also, I am pleased that you continue to keep the advertising separate and away from the text."

"Congratulations on the contemporary format of the *Journal*, Volume 130, Number 1. It is destined to become a collector's item."

"I might say . . . that the *Journal* has, to me, had a drastic positive change under the present leadership. . . ."

"Just a word of congratulations on the format of the first issue of Volume 130 of *The American Journal of Psychiatry*. It is a very convenient size and the print is easily readable. The editors have been doing a fine job."

For these and various congratulatory comments, our sincere thanks.

F.J.B.

BRIEF COMMUNICATIONS

A New Framework for Baccalaureate Careers in the Human Services

BY ROBERT M. VIDAVER, M.D., AND JAMES E. CARSON, M.D.

An articulated human service career "lattice," utilizing three two-year modules, has been developed in Maryland, extending from community college mental health associate programs through baccalaureate and master's degree modules. Graduates of the several curricula work in a variety of community mental health, institutional, and family service roles linked with appropriate civil service classifications. Completion of an educational component qualifies the graduate for the next higher employment role, and, similarly, promotion becomes the ticket of admission to the next academic rung.

IN THE PAST HALF-DOZEN YEARS undergraduate training programs preparing students for mental health careers have become commonplace. Yet in spite of the burgeoning of two-year community college programs (1) and the inauguration of several notable baccalaureate curricula in the social work-psychology fields, few linkages operate across the differing academic levels or connect with the traditional graduate programs. Thus noncollege "new career" programs and associate-degree, baccalaureate, and graduate curricula proliferate independently. Career mobility for the new manpower is impeded, as is their continuing professional education. Their relationship to psychiatry becomes obscured in the process.

In an attempt to ameliorate some of these problems, the Maryland Department of Mental Hygiene, in consort with Morgan State College and five Maryland community colleges, has sought to develop a unified system of human services education. This "lattice" extends from secondary school through three collegiate levels—certificate (one year), Associate of Arts degree, and Bachelor of Science degree—and then articulates with both traditional and nontraditional master's programs.

Antecedents date back to the department's initial tooling up for comprehensive community mental health between 1964 and 1966. Early in the planning of Maryland's centers it became obvious that personnel needs could not be met solely by graduates trained in the traditional professional schools. Not enough students were enrolled and there were too few clinical programs. Nor could the public sector afford the costs of professional salaries as positions multiplied in proportion to the opening of active treatment centers. As the locus of services moved from the custodial institutions to neighborhood centers, large numbers of persons with psychodynamic skills were needed. Fortuitously, reports of successful unorthodox approaches by Rioch and associates (2), Elkes (3), True (4), and Peck and associates (5) and the new careers movement encouraged the department to "think innovative" (6). Wellner (7) had already demonstrated a receptivity among Maryland agencies toward such new manpower types. Abetted by the Southern Regional Education Board's NIMH-supported Community College Mental Health Workers Project (8), the department chose a collegiate vehicle for the training of the new workers.

Consequently, a two-year course of study was formulated by one of us (R.M.V.) (9) and introduced under Kurland's (10) direction at the Catonsville Community College in 1967. Concurrently a parallel curriculum was developed by Schulman (11) at the Community College of Baltimore. Three additional colleges—Essex, Montgomery, and Anne Arundel Community Colleges—instituted comparable curricula between 1968 and 1970, affording accessibility to some three-fourths of the state's population. Simultaneously the department developed civil service job classifications and budgeted positions (see table 1), along with work-study arrangements for the department's employees.

Underlying the structure of the new curricula was the belief that, much as in nursing, beginning professional skills in the human services could be taught at the community college level. The term "beginning professional" deserves special emphasis. It was anticipated that graduates might carry out uncomplicated professional tasks under supervision, adding gradually to their range of re-

Read at the 124th annual meeting of the American Psychiatric Association, Washington, D.C., May 3–7, 1971.

Dr. Vidaver is Chief, Mental Health Care and Services Financing Branch, National Institute of Mental Health, 5600 Fishers Lane, Rockville, Md. 20852. Dr. Carson is Director, Division of Mental Health, Department of Health and Social Services, New Castle, Del.

TABLE 1
Career Lattice Salary Ranges: Interrelationship of Traditional and Nontraditional Workers

Position	Maryland Salary Grade*									
	3 $4,910– $6,472	4 $5,401– $7,097	5 $5,941– $7,806	6 $6,535– $8,587	7 $7.189– $9.446	8 $ 7,617– $10,009	9 $ 8,378– $11,007	10 $ 9,217– $12,110	11 $10,139– $13,321	12 $11,153– $14,654
Psychiatric Aide I, Sr.	X	X	X							
Licensed Practical Nurse (Psychiatric Aide III, IV, V)				X	X	X				
Registered Nurse I–IV						X	X	X	X	X
Mental Health Associate I, II, III**				X	X	X	X			
Mental Health Specialist I, II** (B.S. degree)								X	X	
Mental Health Specialist II, III** (M.S. degree)									X	X
Psychologist I, II, III (M.S. Psychologist)							X	X	X	X

*Salary range based on authorized schedule beginning January 1, 1972.
**As proposed.

sponsibilities as they gained experience. Education of mental health associates has been described elsewhere (1, 9, 12); it is enough to mention here the integration of background behavioral sciences with practicum responsibilities from the first year onward. Students rotate through a variety of institutional and community roles under direct faculty supervision.

Representative of the jobs taken by the early graduates are the following: consultant to the faculty of a Baltimore junior high school, family therapist in association with a privately practicing psychiatrist, "caseworker" on a crisis intervention team, group therapist on a locked adolescent drug ward, and family counselor for a county outpatient clinic. Three associates as a team developed a primary mental health care program for a rural county; others established a behavior modification token economy ward in a state hospital; another associate returned as a full-time faculty member of a college teaching team.

Also noteworthy has been the utilization of graduates by practicing psychiatrists in the team care of patients under Maryland's Medicaid program. Psychiatrist-associate groups have moved to develop mental health "packages" appropriate to the needs of evolving health maintenance organizations (HMOs). Nonetheless, the professional education of the associates is incomplete at the point of graduation. For some, continued professional growth will follow naturally under the supervision of the professional colleagues with whom they work. For others, career mobility or lateral movement into related human service specialties—alcoholism, child care, services to the aged—presents real problems. Mental health associates were not conceived of as comprising a new profession, with its own discrete role, or as a special breed of perennial assistants. They are beginning clinicians who are expected to grow professionally at differing rates and to varying degrees in the course of their clinical work over the next ten, 20, or 30 years. The quality of their continuing professional education takes on particular importance exactly because they are an unfinished, albeit malleable, product at graduation. To ensure the availability of sound, clinically based continuing education the second module of Maryland's three-stage educational lattice was opened at Morgan State College, Baltimore, in September 1970.

The Morgan State curricula, like the community college programs, initially lasted two years; they began, however, where the community college left off. (At first open only to graduate mental health associates transferring in at the junior-year level, the Morgan programs have subsequently developed freshman-sophomore modules identical with the community college curricula.) The Morgan programs are a series of parallel two-year modules whose completion leads to the Bachelor of Science degree. There are three baccalaureate modules: community mental health, child care/educateur, and neighborhood center administration. Other modules under discussion include drug abuse-alcoholism counselor, mental health nursing, and corrections/probation counselor. Each of the modules has its own educational and professional goals and separate courses of study.[1] (See appendix 1.)

There is a common core underlying all third-year clinical coursework and there are shared electives in the fourth year. The two-year modules include 32–36 semester hours in professionally supervised clinical work (one

[1] Tables are available from Dr. Vidaver giving details of the curriculum for the upper division baccalaureate program for Child Care Specialist/Educateur and for the upper division baccalaureate/master's program in Neighborhood Health Center Administration.

semester hour of practicum translates into three actual hours per week in the field); 12–16 hours in advanced behavioral sciences; and 12–16 credit hours of additional general education required by Morgan for the B.S. degree.

Despite the seeming narrowing of professional focus during the senior year, we consider graduates of the Morgan program to be generalists. In the community mental health curriculum, for instance, the students' clinical experience runs the gamut of the human services, from asylums, jails, nursing homes, and halfway houses to orthodox psychiatric outpatient departments, HMO operations, and that host of institutions—e.g., schools, neighborhood action groups, police, senior citizens' centers, recreation programs—where they learn the art of consultation. Within their target community they serve a broad spectrum of individuals whose difficulties span the spectrum of classic diagnostic categories.

THE NECESSITY OF BACCALAUREATE PROGRAMS

Are the baccalaureate programs necessary, particularly in view of the success of the community college programs? Conversely, is a baccalaureate rung justified vis-à-vis our well-developed graduate system (and the tightening job market for master's graduates)? We believe it is justified because the baccalaureate programs serve as a critical link between expanding community college programs and the traditional graduate schools. We believe the ultimate value of the undergraduate mental health worker curricula lies not so much in their generation of new middle-level "assistants," but, rather, in their appeal to "middle-American" youth, many of whom will continue upward on the career ladder, forming a constant source of new professionals comprised of persons heretofore lost to the human service professions. Were the community college programs to prove a dead end, few persons of real talent would choose to enroll. The appeal of the new programs is their open-endedness. A guarantee of the quality of their continued professional growth may, for many, depend on the availability of articulated academic steps. Similarly, later entry into graduate school may hinge on the validity of their upper division baccalaureate education and credentials. Their number is large. Between 1972 and 1975 Maryland's five community college programs will graduate some 120 to 160 mental health associates annually. Perhaps a fourth—30 to 40 graduates—will move directly into upper division curricula. Of the remaining 80 to 110 graduates each year choosing employment, we anticipate that over half (40 to 60 Associate of Arts degree holders) will at varying times in their careers reenter college, either part-time or full-time, to pursue their B.S. degrees.

The reason, then, for the baccalaureate programs is the improbability of the typical community college mental health worker's having access to sound continuing education where he works. While he will have supervision, opportunities for learning new and quite different skills or for taking on higher levels of responsibility may be lacking. Large public institutions have neither the senior staff available for this work nor the proper community models. Smaller, decentralized "storefront" centers lack the diverse staff needed to cover many specialized fields at many educational levels simultaneously. Indeed, indigenous community institutions using the associates in liaison and consultant roles (courts, schools, neighborhood improvement associations) are entirely without expert faculty. Mere exposure is a poor teacher. The baccalaureate programs may function as educational clearinghouses, conserving scarce faculty and practicums and ensuring the continuing availability of a breadth of academic alternatives and levels suited to the heterogeneous needs of the new workers. In addition, the interlacing of core and common electives makes possible lateral movement from one area to another without a waste of academic or experiential skills. Part-time and extension curricula allow for uninterrupted growth without terminating employment—in effect upgrading the employing institution's overall staff competence without reducing its staff numbers.

The second advantage of the bachelor's programs is that they offer an alternative route to professional excellence. That is, while many have advocated the development of middle-level personnel—i.e., motivated and intelligent persons suited to the tedious (and largely unrewarding) aspects of the professional's routine—the concept is unsuited to the existing labor market. No one (or at least not the kind of individual capable of handling sensitive mental health responsibilities) wants to be a perennial assistant.[2] There is strong competition from other careers, many of them available via community college training. Manpower flow, the idea if career-long job mobility, was postulated as a means of attracting persons to these middle-level jobs but without penalizing them against possible future development into full professional status (13). As long as lower echelon jobs were to become stepping stones to a variety of professional roles, then starting at the bottom wouldn't be demeaning or recruitment inhibited. In turn, once there is a flow of middle-level persons upward, new recruits will be attracted into the college programs to replenish their numbers.

If the two-year curricula offer an easy way into beginning professional careers, then the B.S. programs operate to ensure a multiplicity of professional options later. The A.A. graduates are not forever pigeonholed into a single

[2] America has become a "collegiate" nation. By 1980, some 70 percent of all high school graduates will continue on to college. In the human services the word "professional" is synonymous with graduate education. For the foreseeable future, associate degree workers will occupy but a small fraction of the total human services professional pool. The traditional professions, and their continuing flow of new graduates, will act to maintain the status quo. It is a sad truism that nobody relinquishes a position of relative status voluntarily. What leverage has the new noncredentialed breed with state bureaucracies, civil service commissions, medical societies, and the like? Equality of opportunity for the nontraditional workers entails access to the same educational ingredients that go to make today's professional well trained. In fact, the existence of baccalaureate modules makes possible delineation of challenge exams for specific clinical skills without diluting the basic standards of the professions. Equally important, individuals otherwise well qualified might select pieces from the larger curriculum to fill out conspicuous voids in their educational backgrounds.

task-oriented role. Moreover, the bachelor's degree fits in well with most civil service job classification systems, making for improved lateral and upward career mobility. The Maryland Department of Mental Hygiene anticipates an umbrella classification for baccalaureate workers under the titles of Mental Health Specialist I and II, with salary ranges of $9,217 to $12,110 and $10,139 to $13,321, respectively (see table 1).

A third reason for the bachelor's programs lies in their concentration on skills pertinent to the needs of specific populations. Until recently, specialization has been intradisciplinary. For example, psychiatrists choosing to specialize in children study from the perspective of psychiatric practice; psychologists seek to understand the child from their own, albeit overlapping, professional view; while educators use yet another. We suggest that such intradisciplinary approaches to learning run counter to evolving patterns of community services, namely the ascendency of programs to aid target populations—the elderly, alcoholics, children (12). Services become less oriented to pathology as ever-larger segments of the general population utilize mental health services of one kind or another. The delivery of services becomes increasingly a function of experts operating within the fabric of ordinary community life—schools, churches, courts, etc. The expertise needed in the human services spans the various traditional disciplines, each of which makes its own contribution to the whole. Similarly, the education of mental health personnel will become less "profession-centered" and more eclectic, with specialization reflecting the nature of the target—a phase in the life cycle (e.g., aging), a common problem (drugs), or economic status (poverty). The Morgan curricula aim in this direction.

MASTER'S DEGREE MODULES

As has been noted earlier, the Morgan curricula include a parallel series of master's degree modules; these are expected to be developed under an NIMH Experimental and Special Training grant award. The purpose of the graduate programs is threefold:

1. To prepare the baccalaureate graduates with special skills in teaching, clinical supervision, and administration (in their own fields);

2. To train graduates of other health and human service curricula in the several multidiscipline specialties offered (i.e., child care, center administration); and

3. To allow selected individuals of high promise to combine the latter two years of the B.S. degree with the two-year master's program, resulting in a three-year combined program for A.A. degree persons and a five-year program for beginning freshmen. (See appendix 1.)

As envisaged, progression from high school through the master's level is possible without losing a single academic credit via three articulated two-year modules (termed 2 + 2 + 2). Each of the modules—associate degree, baccalaureate degree, and master's—is a self-contained, complete unit, pedagogically viable in its own right. Each leads to advanced clinical roles commensurate with the graduates' newfound sophistication; each also leads to the next higher academic degree. Taken in sequence, the 2 + 2 modules are synergetic, the more specialized content of the upper division curricula expanding upon the more generalist community college (or lower division) module. But there is no pressure to move directly from module I to module II. Jobs are available. The completion of each module offers four options: 1) full-time work, 2) full-time school, 3) combined work and school under part-time arrangements, and 4) lateral shift into the traditional undergraduate or graduate human services programs.

While the sequence can be followed without interruption, it need not be. A person takes the next step, whether employment or schooling, only when it makes sense to him in terms of his own personal life, career goals, or family commitments. Many prefer to intersperse periods of full-time employment between academic modules (13). And for some this may prove the better education. The added time for decisions and the juxtaposition of work with schooling may well result in clinicians who are more mature and more at home with their final career choices (14).

Because the modules are separated by traditional college degrees, they act as juncture points facilitating lateral transfer between career fields or easy movement into jobs before a person invests six, eight, or more years in higher education. Our aim has been to construct a lattice of parallel jobs and their academic counterparts so that completion of the educational component qualifies the graduate for the next higher employment role and, similarly, so that promotion becomes the ticket of admission to the next academic rung. We hope that people will enter the lattice from a variety of levels and personal backgrounds and that they will then join a single, multipotential career mainstream. How far up or across the lattice should one go, and when? These would become personal decisions, yet also instantly renegotiable throughout one's career by way of the lattice articulations and options for lateral transfer.

APPENDIX 1
Community Mental Health Curriculum: Upper Division Baccalaureate/Master's Program

THIRD YEAR (BACCALAUREATE)

Program Courses (credits in parentheses)

Community determinants of individual behavior (4)
Consultation and group therapies (4)
Humanities elective (3)
Speech (2)
Physical education (1)
American history (3 + 3)
Psychology of the exceptional child (3)
Sociology of the family (3)
Mental health electives (6–9 credits from third-year electives, below)
Total credits, two semesters = 34

Electives

Dynamics of health services organization (4, 4, 2)
Urban health problems (3)
Public and community health (3)
School hygiene and health problems—group solutions (3)
Community recreation (3)
Juvenile delinquency (3)
Criminology (3)
Activity therapies: vocational rehabilitation (4); recreational rehabilitation (4)

FOURTH YEAR/FIRST GRADUATE YEAR

Program Courses

Advanced seminars and field assignments (4 + 4)
Humanities elective (3)
Great issues (2)
Political science/economics elective (3)
Clinical electives (6–9 credits from clinical electives, below)
Applied social science elective (see applied social science electives, below) (3 + 3)
Adolescent/drug abuse elective (3)
(First-year graduate students take an additional 8–12 credits from second-graduate-year electives in lieu of Humanities, etc.)
Total credits, two semesters = 33

Clinical Electives

Behavior analysis and environmental design (4, 4)
Group dynamics: special treatment groups (4, 4)
The culture of drug abuse: rehabilitating the young offender (3, 3)
Children, the family, and the community (3, 3)
Community, family, and self-care approaches in retardation (4, 4)

Applied Social Science Electives

Collective behavior (3)
Government and social welfare (3)
Formal institutional structure (3)
Planned change in bureaucratic systems (3, 3)
Public opinion and propaganda (3)
Welfare as a social institution (3, 3)
Urban geography (3)

SECOND GRADUATE YEAR

Program Courses

Community subspecialty clerkships (12 credits from graduate electives, below) (6 + 6)
The community as a self-care system (3 + 3)
Elementary neurobiology (3)
Introductory psychopharmacology (3)
Public health elective (6 credits from public health electives, below) (3 + 3)
Total credits, two semesters = 30

Graduate Electives

Aging and chronic care (6)
Community-institutional articulation problems (6)
Comprehensive family health care (6, 6)
Mobilizing community resources; protest leadership (6, 6)
Alcoholism and suicide prevention (6, 6)
Corrections and parole; indigenous adolescent gangs (6, 6)
Drug abuse: ambulatory care; public and community approaches (6, 6)

Public health electives

Principles of health administration: introductory operations research (3, 3)
Levels of care and manpower utilization (3, 3)
Principles of epidemiology (3, 3)
Electronic data processing and records retrieval (3, 3)

Long-Term Treatment of Tardive Dyskinesia with Haloperidol and Tetrabenazine

BY HAJIME KAZAMATSURI, M.D., CHING-PIAO CHIEN, M.D., AND JONATHAN O. COLE, M.D.

Thirteen patients with tardive dyskinesia were treated with either haloperidol or tetrabenazine for 18 weeks. Haloperidol produced a statistically significant reduction in the frequency of oral dyskinesia, though the effect was most striking during the first two weeks; reversible extrapyramidal symptoms appeared to be negatively correlated with oral dyskinesia. Tetrabenazine also produced a significant reduction in the frequency of oral dyskinesia, with almost complete suppression in two patients throughout the study; the correlation between oral dyskinesia and reversible extrapyramidal symptoms was less clear than with haloperidol. No exacerbation of the dyskinesia was observed after administration of the study drugs was discontinued.

TARDIVE DYSKINESIA or persistent oral dyskinesia has been described as a potentially irreversible neurological condition not infrequently encountered in patients on prolonged neuroleptic therapy. It is characterized by involuntary bucco-linguo-masticatory movements, occasionally accompanied by choreiform movements of the extremities or trunk. A number of large-scale surveys of psychiatric inpatient groups have revealed a prevalence of this syndrome ranging from 2 percent to 30 percent (1–10). Tardive dyskinesia has caused special concern among psychiatrists because the dyskinetic movements appear to persist indefinitely after neuroleptic drugs have been stopped.

Although the condition is rarely severe or incapacitating, the abnormal movements, which are often readily observable, constitute a very undesirable long-term effect from a group of drugs that is otherwise both effective and essential in the treatment of schizophrenic patients.

Tardive dyskinesia has been linked to neuropathological lesions in the basal ganglia (11) and to an excess of dopaminergic activity in these same brain areas (7, 12–17).

At the time this work was done, the authors were all with Boston State Hospital, 591 Morton St., Boston, Mass. 02124, where Dr. Kazamatsuri was Research Fellow in Clinical Psychopharmacology, Dr. Chien is Director of Clinical Research, and Dr. Cole is Superintendent; Dr. Kazamatsuri is currently Professor of Psychiatry, Teikyo University School of Medicine, Tokyo, Japan. Address reprint requests to Dr. Chien at Boston State Hospital.

This work was supported in part by Public Health Service grant MH-16128 from the National Institute of Mental Health.

The authors wish to thank Robert Taylor, M.D., for his neurological evaluations of the patients and Hoffman-La Roche for supplying the tetrabenazine and placebo tablets for this study.

In earlier papers (18–20), we reported the marked short-term clinical efficacy of both a dopamine-depleting drug (tetrabenazine) and dopamine-blocking drugs (haloperidol and thiopropazate) in the treatment of tardive dyskinesia over an eight-week period of gradually increasing dosages of the drugs. These findings support the hypothesis that tardive dyskinesia may result from excessive dopaminergic activity in the brain. Several other investigators have reported that haloperidol (21), tetrabenazine (22, 23), thiopropazate (24, 25), reserpine (26, 27), isocarboxazide (28), or alpha-methyl-dopa (26) were effective in the symptomatic control of tardive dyskinesia. However, all of these trials were carried out over relatively short time periods. No satisfactory and effective long-term pharmacotherapy for tardive dyskinesia has been found to date.

The present paper reports the results of an 18-week study using both a dopamine-depleting drug (tetrabenazine) and a dopamine-blocking drug (haloperidol) for the treatment of patients with severe cases of tardive dyskinesia.

The purposes of the study were twofold. First, we wished to learn whether drugs that showed effective short-term suppression of dyskinetic movements would continue to manifest this effect when administered as maintenance therapy. Careful inspection of the data from our earlier studies leaves one with the impression that the stepwise dosage increases used may have served to maintain the suppression of dyskinetic movements that otherwise would have escaped from drug control. There is a widely held clinical belief that dyskinetic movements break through rather rapidly when they are suppressed by antipsychotic drugs. Second, we wished to determine whether the suppression of dyskinetic movements over a period of several months led to any appreciable exacerbation of the movements when the suppressant drug was discontinued.

SUBJECTS AND METHOD

Thirteen patients were selected for this study. They were all chronic psychotic inpatients at Boston State Hospital who manifested typical bucco-linguo-masticatory oral dyskinesia associated with long-term neuroleptic medication. All of them had been subjects in our previous studies (18, 19); detailed physical and neurological examinations had been completed prior to the initiation of the previous studies. There were eight men and five women, ranging in age from 41 to 63 years, with an average age of 55.8 years. The length of psychiatric

hospitalization ranged from 15 to 41 years, with an average of 29.3 years. Ten patients were diagnosed as chronic schizophrenics, two as mentally deficient, and one as having a chronic brain syndrome.

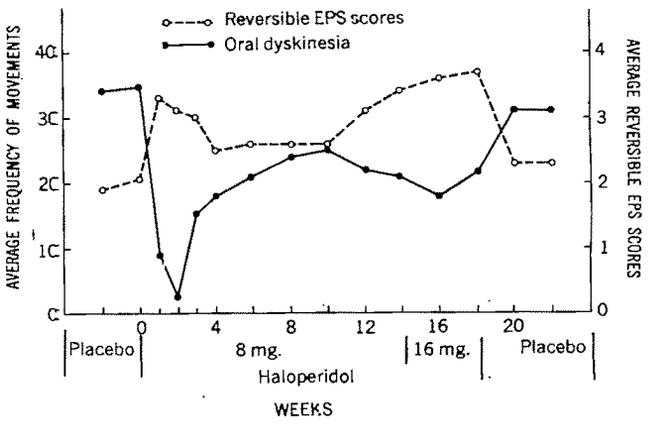
The 13 patients were divided randomly into two groups. In the initial phase, all neuroleptic and antiparkinsonian drugs were completely withdrawn and were replaced by placebo for the first four weeks. Other medications, such as antidiabetic or anticonvulsant drugs, were continued unchanged.

Seven patients received 4 mg. of haloperidol twice a day and six patients received 50 mg. of tetrabenazine twice a day. These dosages were determined on the basis of the findings in our previous studies, which indicated that the majority of the patients with oral dyskinesia responded favorably to either 8 mg. per day of haloperidol or 100 mg. per day of tetrabenazine. It was originally planned that these dosages would be held constant for 24 weeks. However, by the 12th week of the study, it became obvious that the marked reduction in abnormal movements observed during the first several weeks had not persisted for the majority of the patients; this was especially true for the patients receiving haloperidol.

A frequency count of mouth movements (18), done by a psychiatrist blind to the study design, was used to assess oral dyskinesia. The mean frequency of oral dyskinetic movements per minute was obtained at each evaluation. Evaluation was carried out weekly for the first four weeks of drug administration in the study and biweekly for the rest of the study period. Reversible extrapyramidal symptoms were rated biweekly by the senior author (H.K.) using a modified "bilan extrapyramidal" (29). The Nurses Observation Scale for Inpatient Evaluation (NOSIE) (30) was completed every six weeks by the ward nurses, who were also blind to the study design, to assess the ward adjustment of the patients.

RESULTS

Pre-Drug Placebo Period



During the four weeks of the pre-drug placebo period, all the patients manifested typical bucco-linguo-masticatory dyskinesia. The average frequency of oral dyskinetic movements per minute was 34.9 in the haloperidol group and 25.7 in the tetrabenazine group. Little change occurred in either oral movements or reversible extrapyramidal symptom scores during the four-week pre-drug placebo period.

Clinical Efficacy of Haloperidol

Seven patients were given haloperidol at the daily dosage of 8 mg. At the end of the second week, oral dyskinetic movements had completely disappeared in five out of seven patients and were markedly reduced in the other two patients. The average frequency of oral movements was 2.4 per minute. At the end of the fourth week, complete suppression of oral dyskinesia was still observed in four patients. In the other three patients, however, the

FIGURE 1

Changes in Frequency of Oral Dyskinetic Movements and Reversible Extrapyramidal Symptoms During Administration of Haloperidol (N=7)

frequency of oral dyskinesia had returned almost to the levels observed prior to administration of haloperidol. The average frequency of oral movements for all seven patients was 18.0 per minute.

At the end of the eighth week, although complete disappearance of dyskinesia was still observed in two patients, marked suppression of dyskinesia was no longer seen in the other five patients. The average frequency of oral movements was 24.1 per minute. At the end of the 12th week on haloperidol, all the patients manifested oral dyskinesias, even though the average frequency of oral movements was still significantly lower than that observed during the pre-drug placebo period (21.8 versus 34.9, $p < .01$).

Starting at the 15th week, the daily dosage of haloperidol was doubled to 16 mg. Two weeks after the increase in dosage, three patients showed considerable reduction in the frequency of oral dyskinesia. Two other patients, however, developed severe malaise and appeared not to be able to tolerate 16 mg. of haloperidol; the drug was discontinued. The remaining two patients did not show any improvement in oral dyskinesia. Replacement of haloperidol by a matched placebo in the 19th week resulted in a rapid reappearance of oral dyskinesia, with the frequency rising to approximately the pre-drug level in all patients.

Table 1 depicts the clinical efficacy of haloperidol in treating oral dyskinesia, and figure 1 illustrates the changes in frequency of both oral dyskinesia and reversible extrapyramidal symptoms. Comparison of each treatment period with the baseline period by paired t test revealed that haloperidol administration was associated with a statistically significant reduction in the frequency of oral dyskinesia, even though its antidyskinetic efficacy was most striking during the first two weeks.[1] Reversible extrapyramidal symptoms appeared to be negatively cor-

[1] Details of these comparisons and their statistical significance, as well as those for tetrabenazine, may be obtained on request from Dr. Chien.

*The dosage for weeks 2–14 was 8 mg. of haloperidol or 100 mg. of tetrabenazine; for weeks 16 and 18 it was 16 mg. or 200 mg., respectively.

related with the changes in frequency of oral dyskinesia ($r = .6292$, $p < .02$).

Clinical Efficacy of Tetrabenazine

There were no dropouts among the six patients who received tetrabenazine. At the end of the second week, oral dyskinesia had completely disappeared in two patients and was unchanged in the other four patients. As shown in table 1, this split remained almost constant throughout the 14 weeks during which the patients were receiving 100 mg. per day of tetrabenazine. The average frequency of oral movements was reduced from 25.7 to 12.8 at the end of the second week, then increased to 16.8 at the end of the sixth week, and stayed at almost this same level until the 15th week (see figure 2).

The dosage increase of tetrabenazine to 200 mg. per day at the 15th week produced a slight reduction in average frequency of oral dyskinesia. This effect, however, appeared to be a transient one, since an increase in oral dyskinesia was observed at the 18th week, i.e., four weeks after the dosage increase. The replacement of tetrabenazine by a matched placebo resulted in a rapid return of oral dyskinesia to the levels observed during the initial placebo period. During the 18 weeks of tetrabenazine medication, no significant side effects were observed.

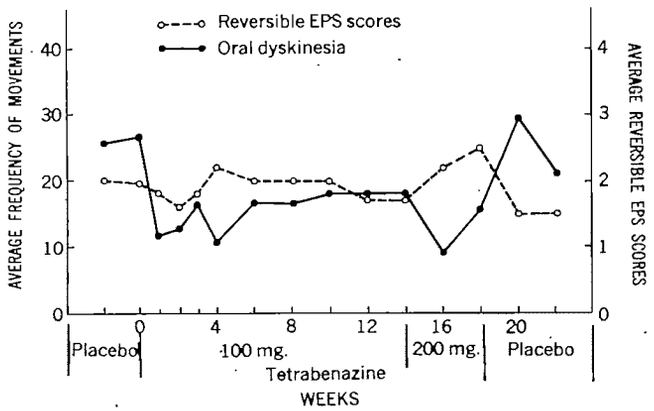
The comparison of each treatment period with the baseline period by paired t test revealed that tetrabenazine administration was associated with a statistically significant reduction in the frequency of oral dyskinesia. The correlation between oral dyskinesia and reversible extrapyramidal symptoms was less clear than in the haloperidol group ($r = .4149$, $p < .20$).

Changes in Ward Behavior

NOSIE ratings were available for six out of seven patients in the haloperidol group and for all six patients in the tetrabenazine group. Although some slight changes in the patients' ward behavior occurred during the course of the study, there was neither clear deterioration nor clear improvement in either treatment group.

DISCUSSION

Studies of drug treatments for tardive dyskinesia involve serious ethical issues. The only kinds of drugs known to suppress dyskinesia reliably are either neuroleptic drugs (e.g., phenothiazines, butyrophenones) or amine-depleting agents (e.g., reserpine, tetrabenazine). In the present study, the aim was to determine whether drugs we had previously shown to suppress dyskinetic movements (haloperidol, tetrabenazine) would be as effective over an 18-week period as they had been over an eight-week period. Haloperidol has been claimed to cause tardive dyskinesia (31–33). Tetrabenazine has not been so implicated, though reserpine has (34).



Since eight-week studies had not led to any worsening in the dyskinesia of the study patients, and the need for a safe and reliable drug to suppress dyskinesia was clear, our ethics committee felt comfortable in approving an 18-week study if it was followed by a placebo period in which adverse effects on the abnormal movements could be determined. Since tardive dyskinesia usually appears after years of neuroleptic drug treatment, it seemed safe to assume that 18 additional weeks of such treatment would not cause any significant change in the underlying disorder.

As the results show, the two treatments did not, in fact, harm the patients. Unfortunately, neither did the treatments prove to be particularly useful in suppressing abnormal movements over an 18-week period. The initial suppression achieved did not persist, and even a doubling of the dosage in the latter phases of the study did not result in optimal suppression. Haloperidol was more effective than tetrabenazine early in the study.

At the present state of knowledge, no specific therapy for tardive dyskinesia can be recommended, although the withholding of all antipsychotic medications for prolonged periods (or the use of such agents in the smallest amounts that will prevent major exacerbations in the patient's psychosis) appears to be the wisest strategy.

FIGURE 2

Changes in Frequency of Oral Dyskinetic Movements and Reversible Extrapyramidal Symptoms During Administration of Tetrabenazine (N=6)

CONCLUSIONS

In order to determine whether dopamine-blocking and dopamine-depleting drugs, which had shown effective short-term suppression of oral dyskinesias in our earlier studies, would continue to manifest this effect when given as maintenance therapy, and whether suppression of dyskinetic movements over a several-month period would lead to any exacerbation of the movements when the suppressant drug was discontinued, we treated 13 patients who had tardive dyskinesia with either haloperidol or tetrabenazine for 18 weeks.

Seven patients were treated with haloperidol (8 mg. per day for 14 weeks and 16 mg. per day for a subsequent four weeks). The clinical efficacy of haloperidol in suppressing oral dyskinesias was observable during the entire medication period, although a striking effect was noticed only in the first few weeks.

Six patients were treated with tetrabenazine (100 mg. per day for 14 weeks and 200 mg. per day for a subsequent four weeks). Tetrabenazine produced almost complete suppression of oral dyskinesia in two patients at a daily dosage of 100 mg. for 14 weeks, without the tendency to relapse during the study period that all the haloperidol patients had shown. A dosage increase to 200 mg. per day produced further suppression of oral dyskinesia in another two patients without any severe side effects.

The suppression of oral dyskinesias appeared to be accompanied by a simultaneous development of reversible extrapyramidal symptoms in the haloperidol group. This apparent inverse correlation was less evident in the tetrabenazine group. No exacerbation of dyskinesia was observed after the drugs were stopped and the patients were returned to placebo medication.

Alcoholism Among Methadone Patients: A Specific Treatment Method

BY IRA LIEBSON, M.D., GEORGE BIGELOW, PH.D., AND RONALD FLAMER

Alcoholism is a frequent complication of methadone treatment. In this study, the reinforcing properties of methadone were employed therapeutically to maintain patients on disulfiram. In the experimental condition, alcoholic methadone patients were given methadone only if they also ingested disulfiram. In the control situation, patients with the same addictions were given disulfiram but were not required to ingest it as a condition of receiving methadone. The results indicated that alcoholism was effectively arrested only while patients were treated under the experimental condition.

WHEN ADDICTS GIVE UP HEROIN in exchange for methadone maintenance, a substantial proportion become alcoholic. The methadone literature indicates that as many as 20 percent of unselected patients going on methadone may become problem drinkers (1, 2), and that, among programs which attempt to screen out applicants who appear to be alcoholic risks, around 10 percent of those admitted to maintenance are subsequently identified as severe alcohol abusers (3). These observations do not seem to reflect merely a concurrent but heretofore undetected problem with alcohol. Rather, methadone treatment itself, perhaps by virtue of its psychopharmacologically, socially, and legally stabilizing effects, appears to precipitate alcoholism in many individuals. Recently compiled statistics indicate that drinking is among the few "markedly increased complaints"—an increase of over 100 percent—occurring as a sequel to the initiation of methadone treatment (4). And among a large variety of possible correlates of maintenance failure examined in a detailed study of 679 patients of Drs. Dole and Nyswander one of the few factors found to be negatively associated with remaining in treatment was "having a problem with alcohol" during treatment. A history of alcoholism prior to methadone treatment did *not* correlate with treatment failure. Problem drinking during treatment, often associated with the abuse of other drugs, was the most reliable predictor of therapeutic failure (5).

Etzioni and Remp recently cited methadone maintenance and disulfiram (Antabuse) treatment as examples of "technological 'shortcuts' to social change" (6)—i.e., impersonal applications of technology to human problems in ways that are inexpensive and require only minimal use of trained manpower. If alcoholism were a necessary link in the causal chain that leads to methadone maintenance failure for some patients, then disulfiram treatment should provide an economical means to enable such patients to stay on maintenance. Because of the highly aversive physiological reaction that occurs almost immediately after the patient takes a drink, disulfiram appears to prevent drinking as long as the patient takes it regularly. Unfortunately, the clinical efficacy of this drug has not been established. The problem is that many patients tend not to take their prescribed disulfiram (7, 8).

Methadone, unlike disulfiram, is a highly reinforcing drug. As Chambers and associates observed: "The retention power of the methadone maintenance modality is without equal in the addict rehabilitation field. It is almost as if this type of patient will continue in treatment regardless of what we do or do not do for them" (5). Stabilized on methadone, the addict has acquired tolerance to the euphorigenic effects of the drug, but he must

take his daily dose to avoid withdrawal sickness (9). Thus methadone operates as a potent negative reinforcer.

Since disulfiram, if taken regularly, can arrest alcoholism, and since these patients are taking a highly reinforcing drug (methadone) every day, one would expect that their alcoholism could be controlled if daily administration of methadone were made contingent on their taking disulfiram. The successful treatment of one alcoholic-narcotic addict by this method over a three-year period has been reported (10). The research described here was undertaken to test the efficacy of this treatment method by comparing it with a control situation in which disulfiram was dispensed but its use was not reinforced.

METHOD

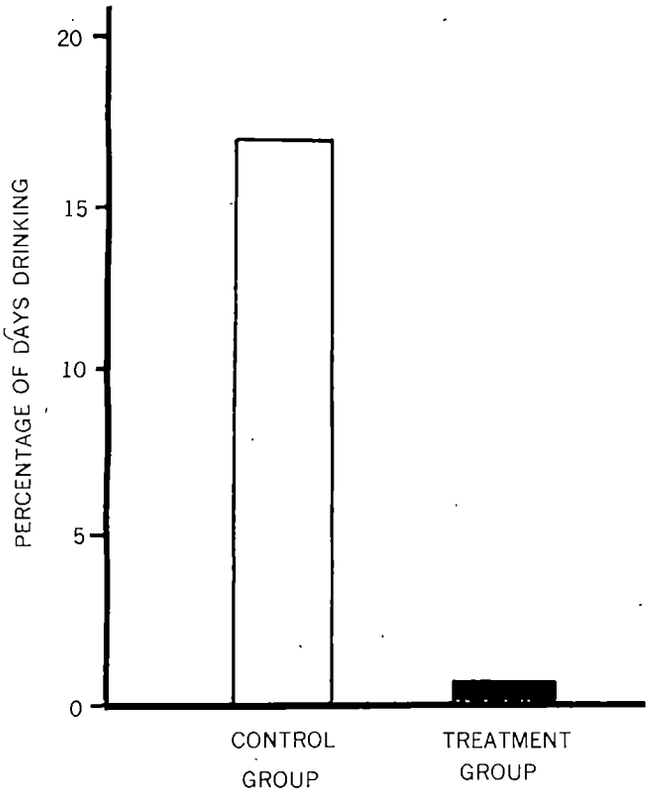
The subjects were addicts who were enrolled in collaborating methadone programs. They had well-documented severe alcoholism and had been screened for medical contraindications to disulfiram treatment.

Two groups of alcoholic methadone maintenance patients were compared as to treatment success. Each group received disulfiram during a mandatory 14-day loading period. Thereafter the experimental group (treatment group) was given their methadone daily contingent on their taking disulfiram, whereas the control group was provided with disulfiram and urged to take it, but it was not necessary for them to take disulfiram in order to obtain methadone.

If patients refused to take disulfiram, and if their drinking problems were considered by the methadone staff to be so severe as to portend their imminent loss to the maintenance program, they could be asked to choose between starting disulfiram and gradual narcotic detoxification, the disulfiram option remaining open during this period. In those cases where hospitalization was required for alcohol withdrawal or where institutionalization appeared desirable while a protective level of disulfiram was achieved, hospital admission was offered. All patients, whether in the hospital or not, were treated the same during the first two weeks. They were seen daily and were required to swallow a well-mixed suspension of 0.5 gm. of disulfiram in water before receiving their methadone.

On day 15 the disulfiram dose was reduced to maintenance level (around 250 mg.) and the patients were randomly assigned to two groups. Those in the treatment group continued to take their drugs as described above. The control patients also visited their methadone clinics daily but were given their supplies of disulfiram weekly and urged to take their daily dose each morning at home, as is the usual practice in dispensing this drug. In the event of treatment failure among the control group, transfer to the treatment group was possible. If a patient was doing well, the treatment staff could transfer him to the control group at their discretion.

Chemical and behavioral data were collected initially and sequentially, via program records, urine tests three times a week, Breathalyzer checks, interviews with patients, and (where ethical) contacts with collateral sources. When the person was accepted for the research program, information was collected about his prior drug and alcohol abuse and possible interrelations between abuse of various substances. For example, patients were asked whether their drinking was heaviest while they were on heroin, methadone, or on neither drug. An initial profile of vocational, familial, and legal adjustment was obtained, and follow-up records in regard to these parameters were kept. Records of attendance, evidence of drinking, disulfiram reactions, and illegal use of such drugs as heroin, amphetamines, cocaine, barbiturates, and meprobamate were also maintained; where indicated, special tests were ordered for other substances liable to abuse.



RESULTS

Six patients have participated in the project for periods ranging from 54 to 147 days (mean 107) after the initial 14-day disulfiram course. Table 1 shows the number of days these patients drank alcohol under treatment and control conditions.

Patients A. (treatment) and W. (control) did no drinking and were not reassigned. Patients P. and B., who were initially assigned to treatment, did little or no drinking under that condition. After the methadone maintenance staff reassigned them to the control condition, they began to drink substantially. Conversely, patients H. and R. were initially assigned to control and drank heavily, with the result that they were transferred to the treatment condition. Their drinking decreased markedly after reassignment.

The difference in the amounts drunk during the treatment and control conditions was greater than this tabulation of drinking days reveals. It was apparent from the patients' accounts of their intake, observed signs of intoxication, and the severity of disulfiram reactions that a

FIGURE 1
Percentage of Days of Drinking by All Six Patients After Random Assignment to Control or Treatment Groups

day's drinking for the control patients was in the range of one to two pints of distilled spirits; whereas in the treatment condition the amounts consumed were invariably small: usually one shot or one beer to test the disulfiram effect. Figure 1 contrasts the drinking of all six patients in terms of percentages of days drinking under the treatment versus the control condition.

To minimize nonrandom factors, which figured in each patient's reassignment, only the initial (random) assignment for each patient is considered. The number of drinking days for the three patients initially assigned to control totaled 22 out of 128 days, or 17 percent drinking days. The number of drinking days for the three patients initially assigned to treatment totaled three out of 274 days, or one percent drinking days. These results are significant at the .001 level, according to a test for difference between proportions.

Although most patients were reluctant to take disulfiram, they all preferred this treatment to discharge from methadone maintenance. In the case of two patients it was necessary to begin narcotic detoxification before they would accept disulfiram. Each day's drinking recorded under the treatment condition resulted in a disulfiram reaction, which was invariably mild—clearly because the amounts drunk had been minimal, as noted above. No such reactions to alcohol were noted under the control condition; this was because (as the patients reported) they had always discontinued disulfiram several days before starting to drink.

All six patients reported that their alcoholism had been most severe while they were on methadone maintenance (as opposed to periods when they were using heroin or were drug-free). Five of the six required brief hospitalization on intake for treatment of alcohol withdrawal. Urine tests positive for drugs except methadone were rare. A trend toward increased employment appeared; this was apparently related to a diminished incidence of intoxication among the patients since starting on the research program.

COMMENT

These results indicate that at least over a short-term period, drinking by alcoholic-narcotic addicts can be arrested by disulfiram when their maintenance on methadone is made contingent on their taking disulfiram. If this treatment method proves to be safe and effective with larger population groups and over longer periods of time, an economical and administratively simple treatment will be available for large numbers of methadone patients with drinking problems. Of course disulfiram will not affect the causes of these patients' drinking any more than methadone treatment gets at the roots of heroin addiction. But as with methadone treatment of heroin addiction, the reinforcement of disulfiram taking may enable these patients to maintain a sufficient degree of stability to adjust to society and perhaps in time to effect some fundamental changes in their life situations.

Marijuana and Other Drug Use by Women College Students: Associated Risk Taking and Coping Activities

BY BEATRICE A. ROUSE, M.ED., AND JOHN A. EWING, M.D.

Study of a random sample of 184 undergraduate women revealed that marijuana users differed significantly from nonusers in various aspects of physical and emotional health, the use of a variety of other drugs, means of coping with anxiety and depression, and risk taking to achieve certain desired mental states. The findings have implications for patient care as well as for drug education and student health programs.

PREVIOUS STUDIES have indicated a high prevalence of the use of medications without professional supervision among college students (1) and among delinquents in particular (2). Our interest included exploring this attribute, which might be considered a drug-taking propensity, as well as studying the psychosocial and health aspects of marijuana and other drug use in a random sample of undergraduate women. Comparisons of marijuana users and nonusers were made in terms of their drug use and their willingness to take psychological, physical, and legal risks to achieve certain desired mental states with drugs. In addition, since collegiate users of illicit drugs were found to be significantly more tense, moody, and depressed (3) than their peers, this study attempted to determine whether the means used to cope with anxiety and depression differed between the marijuana users and nonusers.

SAMPLE AND METHOD

A random sample was drawn from the total enrollment of women students at a large coeducational state university in the southeast. The response rate was 92 percent. A confidential interview was conducted by trained women research assistants who administered a comprehensive questionnaire, a list of coping activities including those used in a previous study (4), and the Eysenck Personality Inventory (5). The research materials were completed by 184 randomly selected women students; their ages ranged from 17 to 27 years, with a mean of 20.5 years. The questionnaire and research methods have been described more fully in a previous paper (6).

In this study the term "users" refers to all those who reported that they had taken the particular drug under study at least once in the past year. Comparisons of marijuana groups, however, are between those who reported having ever used the drug and those who had never taken it. Marijuana users are then further differentiated by their present drug status, i.e., whether at the time of the interview they had discontinued its use or were continuing to take it.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

RESULTS

Primary Sources of Drug Information

Marijuana users and nonusers differed significantly in their primary sources of information concerning drugs in general. Marijuana users relied upon close friends and reading almost exclusively for their information, while nonusers relied on formal lectures and mass media such as television, radio, and films ($p < .05$).

Drug Use in General

The women students in this study used a variety of prescription and nonprescription drugs. In the past year, 93 percent had used alcohol, 26 percent had used marijuana, 17 percent had used tranquilizers, 12 percent, amphetamines or pep pills, ten percent, sleeping pills, three percent, mescaline, and two percent, LSD.

The consumption of a variety of commonly used substances such as aspirin, tobacco, and vitamins was also assessed. Analysis of variance was used, and significant differences were found between marijuana users and nonusers both in the total number of substances used and in the amount currently used compared with that in previous years ($p < .001$).

Table 1 shows the various substances studied. The marijuana users were more likely to use alcohol, tobacco, birth control pills, tranquilizers, and pep pills. These differences were all statistically significant when tested by chi-square analyses. In addition, more marijuana users had significantly increased their use of tranquilizers ($p < .02$), pep pills ($p < .05$), and birth control pills ($p < .001$) in the last year.

Alcohol Use

The use of alcoholic beverages was examined in a num-

TABLE 1
Reported Use of Various Substances in the Past Year, in Percentages

Substance	Marijuana Users (N=58)	Never Used Marijuana (N=126)	Significance
Alcohol	100	89	p<.05
Aspirin	95	98	n.s.
Vitamins	67	67	n.s.
Tobacco	64	40	p<.01
Birth control pills	47	22	p<.001
Tranquilizers	26	13	p<.05
"Pep" pills	24	6	p<.001
Laxatives	22	26	n.s.
Sleeping pills	17	11	n.s.
Diet pills	17	11	n.s.

ber of ways in order to determine whether marijuana users had indeed made marijuana, rather than alcohol, their drug of choice.

As shown in table 2, the total alcohol intake for the last year was greater for marijuana users than for nonusers (χ^2 = 13.82, d.f. = 2, p < .001). Total intake was calculated from a detailed examination of the kinds of alcoholic beverages consumed, the usual amount and frequency of each beverage type, and the volume equivalents of absolute alcohol. For example, a student who drank one or two beers a week would consume less than 4,000 ml. for the year; about four oz. of distilled spirits on most days would result in less than 16,000 ml.; and the equivalent of over a fifth of whisky per week would result in more than 16,000 ml. for the year.

Marijuana users also reported drinking regularly and more frequently than nonusers. Sixty-nine percent of the users and only 50 percent of the nonusers drank at least once a week (p < .02). The more regularly the students drank, the more reasons they gave for drinking. It is interesting to note the tendency for more marijuana users (16 percent) than nonusers (seven percent) to drink to alleviate menstrual distress.

The marijuana users' own appraisal of their drinking appeared to be reasonable; this appraisal differed significantly between the groups (p < .001). More marijuana nonusers considered themselves abstainers, while more users considered themselves frequent, moderate drinkers. None of the students characterized themselves as heavy or excessive drinkers.

Marijuana users had begun drinking alcoholic beverages (discounting occasional sips during childhood) at a significantly earlier age than nonusers (p < .001). The mean age of first drinking for marijuana users was 17.0 years and for nonusers, 18.0 years. Also, those who continued to use marijuana had begun drinking at an earlier age than those who had discontinued its use (p < .05).

Marijuana Use

At the time of the survey, 17 percent of the sample were currently using marijuana, 15 percent had used it but were no longer doing so, and 68 percent reported that they had never used marijuana. The mean age of first marijuana use was 19.9 years.

Twenty-nine percent of the users had tried marijuana only once, and only 18 percent had taken it more than ten times. Many of the users had smoked less than one marijuana cigarette, that is, they shared one or two with other members of a group. The usual amount smoked is shown in table 3; 48 percent generally smoked no more than one marijuana cigarette on any given occasion.

Table 4 shows the maximum amount ever smoked at any one time. Continuing users smoked a significantly greater amount; 53 percent of them had smoked a maximum of five or more marijuana cigarettes at one time.

Reasons for Use or Nonuse of Marijuana

The primary reasons given for the first use of marijuana were curiosity (93 percent), urging of friends (17 percent), and "wanting the good feelings people said marijuana gave" (14 percent). More of the continuing users first took marijuana for the good feelings it reputedly produced (p < .05). Those who discontinued its use did so because of a low level of gratification (52 percent), legal consequences (48 percent), unavailability (19 percent), and health (15 percent).

Most of the women students had never used marijuana, even though 48 percent of them reported that they had had opportunities to do so. Several reasons for nonuse were cited: undesirable psychological or physical effects (28 percent), lack of desire for or interest in marijuana (24 percent), lack of need or purpose for using marijuana (18 percent), and legal prohibitions (17 percent).

Backgrounds of Users and Nonusers

Socioeconomic status, present religious status, and academic major differed significantly between users and nonusers. Marijuana users were predominantly from the upper socioeconomic strata as measured by the Hollingshead two-factor index (7); 92 percent of the students from blue-collar and nonprofessional backgrounds had never used marijuana (p < .01). The majority of the students remained in the religion in which they were raised; marijuana users, however, were more likely to indicate that they were no longer associated with any organized religion (p < .001). Significantly more marijuana users than nonusers were majoring in the humanities, and fewer were in nursing and health education (p < .001).

TABLE 2
Comparative Consumption of Alcohol in the Past Year, in Percentages

Alcohol Consumption	Marijuana Users (N=58)	Never Used Marijuana (N=126)
0–4,000 ml.	19	81
4,000–16,000 ml.	39	61
More than 16,000 ml.	59	41

TABLE 3
Usual Consumption of Marijuana on a Given Occasion

One or less	18	10	48
Two	6	9	26
Three or more	3	12	26

There were no significant differences between the groups on age or on extraversion and neuroticism as measured by the Eysenck Personality Inventory.

Activities Found Helpful When Depressed or Nervous

The students were asked to indicate whether each of 14 listed coping activities had been helpful to them when they were depressed or nervous. Table 5 indicates those activities which were found helpful to a significantly different degree by the two groups. Users were more likely to find drinking, smoking, sexual activities, and medicines other than tranquilizers helpful. Nonusers, on the other hand, felt helped by religious activities. The activities used most often by the users when depressed or nervous were smoking and solitary activities ($p < .05$), while nonusers more often resorted to physical activities as a means of coping.

Desired Mental States and Associated Risk Taking

The students were presented with alternative pairings of four mental states and asked to choose in each case the one they desired. The one chosen without exception was considered the preferred mental state. Eleven percent of the students, primarily nonusers, had no definite preference. Significantly more users preferred inner awareness and hallucinations, while the nonusers preferred exhilaration and rapid thought ($p < .001$).

When asked to indicate which mental state from a list of 14 they would like to achieve more often than they did now, significantly more marijuana users wanted more freedom from depression and more unusual thoughts or associations ($p < .05$).

The students were then asked to consider the desirability of each of the 14 mental effects if it were to be achieved by using: 1) a drug that had no physical, psychological, or legal risks, 2) marijuana, 3) LSD, and 4) amphetamines. The subjects were asked to take into account the risks associated with each of the three drugs specifically named.

Table 6 shows the desired effects that the students were willing to achieve with a drug if it had no associated physical, psychological, or legal hazards. While significantly more marijuana users were willing to use a drug to achieve most of the effects, substantial numbers of nonusers were interested in a safe drug for only certain very select desired effects; 76 percent of the nonusers were willing to take a risk-free drug to achieve thinking more rapidly and logically, and 67 percent to achieve increased sensory awareness, i.e., of sights, sounds, and music.

Table 7 shows the desired mental states and associated hazards that marijuana users and nonusers were willing to risk with marijuana and the amphetamines. Marijuana users were more willing to take psychological or health

Exhilaration	9	2	3
Social facility	9	2	2
Unusual thoughts	7	2	2

risks than legal risks, while nonusers rarely wanted to risk any of the associated hazards for any of the desired effects.

Few of either the marijuana users or nonusers considered the risks of LSD worthwhile, and, indeed, we found only five students who had ever used it.

Physical and Emotional Health

Significant differences between marijuana users and nonusers were also found in terms of various aspects of physical and emotional health. Significantly more marijuana users reported sleeplessness ($p < .05$), violent or frightening dreams ($p < .01$), having ever been involved in automobile accidents ($p < .001$), having been involved in automobile accidents in the last year ($p < .05$), and consultation with a psychiatrist ($p < .01$). Also, there was a tendency for more marijuana users to have had injuries requiring hospitalization and to have consulted a physician for "nerves."

DISCUSSION

In our various investigations of drug use among enrolled students, we have found that the use of marijuana in the college population studied appears to be of low dosage, infrequent, and associated with upper socioeconomic backgrounds and an abandonment of organized religions in both undergraduates and graduates, regardless of sex (6, 8). The psychosocial associations found in this region (southeast) appear to be similar to those found in other areas of the country (9–12).

Even though a broad definition of "marijuana user" was utilized in this study, significant differences between the groups were found. Marijuana users differed in their primary sources of drug information as well as in their actual use of a variety of substances. Women who smoked marijuana reported significantly more use of substances such as alcohol, tobacco, tranquilizers, and birth control pills. Those who had begun drinking at an earlier age were more likely to smoke marijuana. The finding of significantly more continued and regular drinking among marijuana users was supported by a further study of undergraduates (13) but not of graduates (8).

Both marijuana users and nonusers seemed receptive to the concept of altering moods or mental states with a drug. The nonusers, however, were more selective as to the risks they were willing to assume and the particular mental state desired. Nonusers were interested in a safe, legal drug that would improve their rational processes or increase their sensory awareness. They wanted increased social facility and freedom from depression. Marijuana users, on the other hand, appeared to be seeking all kinds of new stimulating experiences, particularly those resulting in a change of consciousness and sensory and inner awareness.

Whether the users are willing to assume more risks or perceive fewer hazards (14) needs further study. The greater number of automobile accidents and of injuries requiring hospitalization among users suggests their actual involvement in more situations with physical risks. Since marijuana users were usually also regular drinkers, the determination of the effects of marijuana should be done cautiously. The frequency of automobile accidents reported among marijuana users, for example, may be due to the effect of alcohol alone, marijuana alone, or the two in combination.

The differences between the groups in activities found helpful when depressed or anxious also indicate a greater willingness on the part of the marijuana users to take substances in order to deal with their feelings. These results are comparable with the findings from our study of women graduate students (8).

Because the women marijuana users were also more likely to consult either a psychiatrist or a physician, these findings have implications for patient care as well as for programs of drug education and student health.

DISCUSSION

GEORGE S. GLASS, M.D. (Bethesda, Md.)—That marijuana use has become a ubiquitous phenomenon in present-day American culture is reflected by the high percentage of users under age 30 in high school, college, and graduate school. This study documents marijuana use in still another population—26 percent of the women students at a southeastern university. Other studies have found that up to 60 or 70 percent of college populations have used marijuana (1). The variability in reported rates is due to many factors, including the definition of drug use, the sex of the user, the location of the study, and the individual personality differences, including psychopathology, of the users (2, 3).

This study defines a marijuana user as anyone who has ever smoked it—even a single puff. In fact, the authors found that 42 percent of the students they classified as "users" had not smoked even ten marijuana cigarettes in their lives. Only 11 percent of the total sample had smoked over ten marijuana cigarettes. In a relatively large sample such as this, it would have been more useful to subdivide the user category into experimenters and frequent users, with perhaps ten cigarettes as the dividing line. The data would then be more meaningful in documenting whether there is an increase in the psychopathology of users: whether there is an increased need for coping activities and whether smoking marijuana has itself become a coping activity. It is to be hoped that later work will further elucidate these points.

Considering the broad definition of drug use, the low percentage of users reported in this study is important and probably related to several factors. One is the sex of the users, as there is generally a higher usage rate among men. A comparison group of men from the same school would have provided an interesting contrast. A second factor is the location of the study, since usage rates are relatively higher in the northeast. A third factor is the type of college from which the sample is drawn, as higher rates of marijuana use are found in colleges that emphasize academic independence and personal freedom (2). This is reflected in this study by the higher percentage of users who were liberal arts majors rather than science or nursing students.

This paper also elaborates on various demographic and psychological parameters of drug users. It might have been helpful to cast the authors' findings in different terms, such as the user's relationship to authority and to her family, or her degree of self-control.

The authors have demonstrated that drug users were from higher socioeconomic groups and used alcohol at an earlier age. They state that drug users were less involved in their original religions, but do not explain how this important and provocative point was documented.

These characteristics of marijuana users reflect parental background and upbringing. An individual's relation to authority is largely a result of his family's structure and his perception of parental values. Thus, some hypotheses could have been explored to explain the differences of behavior reflected in the data. For example, if users began drinking at an earlier age, was this an individual act of rebellion against strict or even duplicitous parental authority? Or was the drinking done with parental support, in a home atmosphere in which societal limits were examined and questioned? Unfortunately, the authors do not formulate any conclusions on this important point; the addition of a scale to assess response to authoritarianism might have been useful.

The authors view marijuana use as a mode of coping or of trying to alter anxiety, moodiness, and depression. Their presentation is rather prejudicial, since their findings could also be attributed to the heavy alcohol consumption of part of this population. Pharmacologically, though, marijuana does have some tranquilizing effects (4).

Starton's work on drug use in Viet Nam provides evidence that marijuana may be used at times of stress for tranquilization, or as a coping activity. He found a higher incidence of marijuana use among military personnel leaving Viet Nam than among those who had just arrived (5). He related this increased use to stress and combat rather than simply to drug availability or social approval. It is of interest that while marijuana use began under the stress of the military situation, many of the individuals planned to continue to use it when they returned to civilian life. In effect, what had begun as a coping activity became a pattern that would be continued without stressful stimulus. What is uncertain is whether drug use then remains a coping activity for these persons, or whether it has become an acceptable recreational activity.

These studies may indicate that if the legal consequences of smoking marijuana are reduced and if the health risks are further clarified and found to be small, the actual risks of smoking it become slight. The percentage of experimenters may well increase, as was suggested by this study, but the percentage of heavy users may remain close to the same level that the authors found—ten percent of the population. Whether these heavy users are also those individuals who would be heavy drinkers, with a need to cope through the use of one drug or another, still remains to be clarified.

Postgraduate Training in Child Psychiatry: The Content of the Curriculum

BY B.G. BOOTHROYD BROOKS, M.B., D.P.M.

In order to help others in the field arrive at a more precise knowledge of what constitutes a satisfactory curriculum of postgraduate training in child psychiatry, the author presents the content of a recently designed two-year program. It has been planned to achieve the maximum possible coordination of courses and to provide broad clinical experience.

AT THE ANNUAL MEETING of the Society of Professors of Child Psychiatry in March 1972, there was much confusion as to what should be the content of undergraduate and postgraduate teaching programs in child psychiatry. A computer search of the world literature had revealed the extreme paucity of articles dealing with this fundamental topic.

It is a familiar experience of those accustomed to attending meetings on the design of university teaching programs that discussion tends to stick at the old familiar issues: the general philosophy and methodology of teaching, the transmission of attitudes currently in vogue or otherwise regarded as desirable, the need for a holistic, or other, approach, and, of course, conflicts among factions of differing theoretical viewpoints. These heated discussions apparently do not lead to progress in the creation of a curriculum of postgraduate training that is scientific and systematic.

Although it is often neglected, the fundamental question of actual curriculum content persists. What should be taught? What areas of knowledge should be covered? What facts should be demonstrated? What evidence should be critically evaluated and discussed? There is fear of losing significance in the complexity of detail, but the detail itself is not without significance. Complexity may be feared, but its recognition may be the beginning of wisdom.

This report describes a recently designed postgraduate teaching program in child psychiatry. Its objective is not, of course, a diminution of the arguments surrounding this subject, but rather, the achievement of a more precise knowledge of exactly what we are arguing about. I appreciate the fact that no syllabus can give an adequate picture of the vitality and fascination of a course of study or of the laxity or rigor with which it is carried out. It might, however, be regarded as unwise to attempt to remove, in one short article, all the mystery surrounding the question "Just what is child psychiatry?"

The suggested academic program extends over two years and comprises seven courses.[1] Successful graduates of the program, which was started in September 1972, are to be awarded the degree of M.Sc. in the Faculty of Medicine of Memorial University of Newfoundland.

THE CURRICULUM

Course 1: The Scientific Principles of the Measurement of Child Development

This course includes discussions of the concepts of intelligence, educational attainment, personality, social development, language development, physical growth, and motor and perceptual development. The scope and limitations of the measures of these developmental variables are discussed and demonstrated. The course consists of 15 two-hour sessions in the first year.

Course 2: The Methodology of Scientific Research Applied to Child Mental Health

This course considers the principles of research meth-

Dr. Brooks is Assistant Professor of Child Psychiatry, Memorial University of Newfoundland, St. John's, Newfoundland, Canada; he is also Director of Child Psychiatry, Dr. Charles A. Janeway Child Health Centre, St. John's.

[1] A detailed and up-to-date bibliography related to each session of each course is available from the author.

odology, including the formulation of testable hypotheses, survey methods, sampling techniques, questionnaire design, interview techniques, the construction of interview schedules, biostatistics, the use of computers, and preparation of scientific papers. It provides the students with sufficient background to undertake a research project of their choice; this project forms the subject of a dissertation presented at the end of the second year. It also enables them to critically evaluate the major scientific investigations in child psychiatry that are covered in the appropriate parts of the course. This course consists of 45 two-hour sessions in the first year. Three hours per week for 75 weeks are allowed for preparation of the dissertation.

Course 3: The Normal Development of the Individual Child

This course deals with the development of the child from infancy to adulthood and includes critical descriptions and evaluations of the modern theories of mental and personality development in infancy, childhood, puberty, and adolescence. The course consists of 45 two-hour sessions in the first year.

Course 4: Social Influences on Child Development

This course considers the socialization of the child and the influences of environmental variables. It includes the scientific study of the family, parent-child relationships and behavior, child-rearing practices, maternal employment and multiple mothering, social and sensory deprivation, the effects of parents' physical and mental illness upon the child, bereavement and the effects of the loss of a parent, the problems of family disruption, single-parent families and the broken home, adoption, and foster homes. The course consists of 30 two-hour sessions in the second year.

Course 5: Emotional Aspects of Physical Illness in Childhood

This course deals with the consequences of physical illness in children and its impact upon parents and siblings, chronic handicaps, the effects of admission to the hospital, and the child with a fatal illness. The course consists of 15 two-hour sessions in the first year.

Course 6: The Childhood Psychiatric Syndromes

This course considers a number of topics, including: the classification, epidemiology, detection, and categorization of psychiatric disorders in children; the clinical features and natural history of each syndrome, psychosomatic disorders, psychoneurotic disorders, psychoses, antisocial disorders and delinquency, sexual disorders, and depression and suicide in childhood and adolescence. The course also covers disorders of speech and language, educational and learning difficulties, and reading difficulties. The remaining topics covered are neurological disorders in childhood, the concepts of brain damage and cerebral dysfunction, the hyperkinetic syndrome, mental retardation, epilepsy in childhood, temper tantrums, thumb-sucking, nail-biting, tics, delusions, hallucinations, fire setting, refusal to attend school, enuresis, and encopresis. The course consists of 60 two-hour sessions in the first and second years.

Course 7: Treatment in Child Psychiatry and Child Psychiatric Services

This course includes a consideration of various modalities of intervention and their appropriate selection. Treatment modalities considered include individual and group therapies with children and adolescents, family therapy, behavioral and conditioning techniques, remedial education, and drug treatment in child psychiatry. Other modalities discussed are community services as treatment, child guidance clinics, child psychiatric outpatient clinics, day-care units, residential care in schools and hospitals, consultation to schools, social and welfare services, and the scientific evaluation of treatment and follow-up studies in child psychiatry. The course consists of 90 two-hour sessions in the first and second years.

DISCUSSION

This academic program takes up four half-days per week of the two-year course.[2]

The scheme of the program enables the courses to be coordinated with each other. For example, the child psychiatric syndromes related to infancy are considered at the time that the course in normal development is dealing with infancy. The program has, in fact, been planned in detail to achieve the maximum possible coordination of courses.[3]

Every fifth week there are sessions called Survey—Question—Revise—Evaluate (S—Q—R—E). Each of these sessions may be used for any or all of these purposes. This built-in provision allows great flexibility and ensures that no topic is neglected and that important topics are stressed by reemphasis.

Experience in the practical aspects of child mental health care is provided in the university's department of child psychiatry. This training, which takes up an additional four half-days per week throughout the two-year course, enables each student to have experience in ongoing care on an individual and on a group and family basis. A balanced clinical experience is provided that covers outpatient assessment and treatment of children and adolescents, all present modalities of treatment, inpatient experience, and experience in consultation with other disciplines. This, together with the academic program, which provides the scientific basis of sound assessment and treatment, gives the students experience in high-quality patient care in the community as well as in the hospital setting.

The remaining two half-days-per week are used for a

[2] A diagram showing the integration and sequence of the courses is available from the author.

[3] Two diagrams showing the coordination of courses and outlining the specific content of the two-year program in detail are available from the author.

series of organized visits and seminars. For example, visits to schools with children of all ages and all socioeconomic groups supplement the course on the normal development of the individual child. At appropriate points in the course, visits are organized to the various community services and agencies dealing with children who are socially, mentally, and physically handicapped. Seminars place due emphasis upon such problems as mental retardation, educational handicaps, juvenile delinquency, and nonmedical use of drugs by children and adolescents; and appropriate agencies and institutions are visited at appropriate times in the course.

A Case of Capgras Syndrome

BY M. T. HASLAM, M.D., D.P.M.

The Capgras syndrome in a 32-year-old woman is described. While showing some affective and schizophrenic features, the syndrome appears to have retained its purity over a period of eight years. A good remission has been maintained recently through the use of long-acting phenothiazines. Case material, including letters, is presented and a brief summary given of the historical origins of the syndrome.

IN THE CAPGRAS SYNDROME, first described by Capgras and Reboul-Lachaux in 1923 (1), the subject holds to an unshakable belief that a double has replaced some person he knows well. The syndrome had in effect been described earlier in Plautus' play *Amphitryon*, in which the god Mercury assumes the appearance of Sosi, Amphitryon's servant, and becomes his double—hence the French name for the syndrome, "L'illusion des Sosies." Another example is found in Dostoevsky's *The Possessed*, written in 1871.

Even if other psychotic features are present, the delusion of a double is the dominant feature in the syndrome. The Capgras syndrome is rare but appears highly specific, with a typical clinical pattern and psychopathology. The "illusion of Frégoli" is a similar condition in which a patient identifies a persecutor in several apparently quite dissimilar persons (1, p. 2). But in the illusion of Frégoli there is an affirmation of *imaginary resemblances*, while in the illusion of Capgras there is a perception of *nonexistent differences*, resulting in a negation of identities. A further subdivision, "illusion of intermetamorphosis" was described by Courbon and Tusques in 1932 (1, p. 2); here the patient believes that persons in his environment interchange with one another.

Capgras' original case involved a woman who appeared to be in a chronic paranoid state; she complained that "doubles" had replaced various persons in her environment. This case and others were reviewed by Coleman in 1933 (2). Todd and Dewhurst (3) described seven cases in 1955. Coleman's case, although not typical, appears to be the first case report published in England. The syndrome is reviewed in Enoch, Trethowan, and Barker's book *Some Uncommon Psychiatric Syndromes* (1). In general these conditions are considered in France to be disease entities in their own right, while in England the cases have tended to be seen as associated with other psychiatric illness.

CASE REPORT

The patient first appeared in 1961 at the age of 32, showing disturbed behavior and believing that people were persecuting her because she did not smoke.

There was little of relevance in the family history. Her parents were dead; there was one sister with whom the patient kept in touch. The patient was born in London and had an uneventful schooling and early life. She worked as a clerk in the Civil Service until her first illness. Since then she has had eight admissions. A delusional system formed, relating originally to people following her who had some special connections: these people appeared in different persons in the street, as is described in her first letter, which follows. Later in the illness a change in her fiancé became the dominant feature, followed in a further relapse by similar thoughts relating to her sister. In 1968, treatment with long-acting phenothiazines was commenced, and the patient remained well until August 1970, when a relapse due to accidental discontinuance of the drug occurred. She was paranoid and believed her fiancé had been replaced by a man who was homosexual. This related to her own frustration concerned with failures of sexual function during the prolonged engagement. Treatment was recommenced and she again improved, although she remained rather belligerent, and in November 1970 she still thought that her fiancé, because he behaved differently, had to be an imposter. By March 1971, however, she appeared well and remained at work, continuing on intramuscular doses of fluphenazine decoanate, although a letter dated October 22, 1971, suggests that she still held to her underlying delusional belief.

Dr. Haslam is Consultant Psychiatrist, Clifton Hospital, York YO3 6RD, England.

Quotations from Her Letters

November 27, 1968

I am hampered by being dogged by a boy of about 15—who seems unable to exist without my notice of him—He breaks up every household I enter. If I cross the road to get away from him another one appears on the other side. I have come to the conclusion he must represent the Infant Spanish Pretender, a son of Greece and Spain. I believe this person also upholds Peter Townsend.

July 17, 1970 [to the Home Secretary, enclosing details of some of her sister's belongings]

There was a time before putting me in hospital some years ago when she removed the bolt from the toilet door, and generally behaved in a way quite unlike herself. *This* house has an open toilet. My fiancé who lived in this house moved here in 1949. He is listed by himself in the Directory in 1957 yet he claims his wife was here. From the discrepancies which have arisen since I have been here it makes one wonder whether his wife when here actually knew when he *was* here and when he was *not* here. She had car number 3213V. Then it suddenly changed to 3218V. She [sister] may have changed very much. But I am sure there has been foul play somewhere and they are covering it up with references to the nobility. Yet the Royal Family have become quite informal. I am tired of trying to solve these riddles. They stand in the way of my marriage. If it is not explained I shall be forced to the conclusion that the nobility have murdered my sister, and the church may have had a hand in it!

October 12, 1970

I have just been to see Roger in hospital and he seems much worse. But there is a very awkward issue. You see the night when he ducked out and went to the river, somebody who knows my fiancé told me that he had been seen in a definite vicinity [in this district] between 10:30 and 11 p.m. In fact I have tried to find contact with the real Roger for a long time but nobody would help me. This is the first time I've been given a definite clue. I thought these others must be acting for him. He *must* know. What on earth can he be doing? When I knew him he couldn't afford to live anywhere but his own home. It put me in an awkward position and I must say it seems to me that the present sufferings of the Roger in hospital are surely caused by the silence of the real Roger.

October 13, 1970: She stated to the mental welfare officer that he had taken "the wrong Roger" to the hospital and that the real one was still at large.

October 13, 1970

As long as this isn't known the hospital is treating the wrong person—I mean he may be quite different from the one in their records. . . . Somebody will have to find the real Roger, because in his mind in more lucid moments the one in hospital is talking of selling up. You see I don't know where he came from in the first place, or what he was before, but it must be enough to split anyone's mind. The one who went to Morecambe with me said he was a policeman.

October 22, 1971

I wrote to Securicor. They informed me the photographs I have of my fiancé are of three different men. However, they sent someone to the house to question this person and he said he had lived there for 20 years so he must be all right. Everyone, the Government, his brother and friends accept him, so as far as I can see there is nothing more to be done.

DISCUSSION

The Capgras syndrome is said to occur at any stage of an accompanying psychosis but when it occurs it tends to dominate the clinical picture. It is interesting how often the words "double" and "imposter" are used to describe the misidentified person. An important feature is the specificity of the double. It is a key figure in the life of the patient at the time; usually it is the spouse. The individual appears to see changes in the partner or to externalize changes in himself that are misinterpreted to create a new "bad" individual who seems to have totally replaced the other. Paranoia is therefore often present; the disorder is one of conaesthesia (ego feeling).

In the case report given here the delusion commenced with the patient's feeling that she was being followed by someone who represented, or was, Royalty. This shows many similarities with the illusion of Frégoli. The delusion then crystallized onto her fiancé, who seemed changed; this in fact began at a time when the fiancé had developed a schizophrenic illness. In later stages the patient's sister also was seen as involved in some kind of change or foul play.

During some phases of her illness the patient manifested a thought disorder of the schizophrenic type and also, in other phases, an affective change, but the dominant feature continuously was along the lines of Capgras' original description. The underlying disorder, however, appears to be one of perception, with concrete thinking. This perceptive disorder appears to explain the misinterpretations, which in the fiancé's case were based on a personality change due to illness, concerning which the patient failed to show insight.

Our patient's illness—and indeed most of those described under the Capgras syndrome—show such a perceptive disorder and are most probably basically schizophrenic in origin.

Treatment has been with phenothiazines; there has been a marked and lengthy remission on fluphenazine decoanate. The patient's relapse on one occasion appeared to be related to a temporary discontinuation of the drug.

LETTERS TO THE EDITOR

Even Mental Health Jargon Can Be Funny

SIR: Many different types of group therapy or group interaction have been used in recent years with employees not only in industry, but also in the mental health community. In order to keep our thinking in the proper perspective, it might behoove us to pay some attention to what those among us who are nonclinical personnel think about some of these endeavors.

After being involved in such group encounters and self-introspection activities, some of the staff members at my mental health center adopted the appropriate life-style and conversational mode, which to some of our nonclinicians seemed laughable at best. In response to their daily use of mental health jargon some of our more rational and well-put-together staff members submitted the following humorous interpretations to me. I think these would be amusing enough, and maybe even carry sufficient learning value, to be included in the *Journal* for those who somehow forget that we live in a very real world in spite of our need to compartmentalize certain events for study.

The interpretations follow:

Useful Phrases for Hiding Confusion and Ignorance

When you are put on a spot to give an explanation or opinion, or comment on a relatively controversial matter, the following phrases inserted at the beginning of every fourth sentence usually will give the impression of calm, organized thinking and honesty (while thoroughly confusing the other parties in the conversation). These phrases also offer increased disorientation among listeners when used in conjunction with long, obscure words, such as, "mental health conceptualizations," "functionalistic," "therapeutic," etc. Remember, however, that it is helpful to spice your sentences with contemporary jargon such as "rap," "plug into," or "groovy" so as to keep you on the same level as your audience.

Examples: "I get the feeling that . . ." (insert appropriate accusation and criticism of the person whose arguments are too good).

"What I hear you saying is . . ." (insert twisted version of the statement of other speakers; exaggerations are good here).

"I guess what I am trying to say is . . ." (repeat verbatim whatever previous sentence in your conversation sounds the most intellectual).

"I think what he is trying to say is . . ." (insert your opinion on the matter at hand).

"One thing that turns me off is . . ." (give a typical paranoid statement that people are afraid of change, too establishment, lack of change, how bad the food tastes, etc.).

"I think we should get this out in the open . . ." (insert appropriate rumor and ask to be excused to go to the john).

All of this may sound somewhat ridiculous, but I truly believe that it expresses the feelings often held by those with whom we fail to communicate on a realistic, everyday level.

Cuyahoga Falls, Ohio

Female Patients: Intractable or Victims of Chauvinism?

SIR: Dr. John H. Houck's article "The Intractable Female Patient" (July 1972 issue) reflects two symptoms with which the male psychiatrist is all too frequently and intractably afflicted: 1) chauvinism toward female "patients," and 2) the tendency to play God.

I would summarize the gist of Dr. Houck's article in the following manner: Childish but dominating and manipulative female "patients" (with childish but passive "husbands") who find their way into psychiatric hospitals pose a difficult problem. This problem can, however, be resolved by means of the following manipulative efforts on the part of the psychiatrist: Return the "patient" to the community and to her former social roles of wife and mother, which she has been rejecting, and push her away from her characterologic role of childish manipulative dominance toward one of submissive tractability. In addition, encourage her husband to play the supporting role of the strong, dominant, father-like husband in this conjugal drama. The reader is warned, however, that the woman (still referred to as the "patient" although now expected to be a "wife," "mother," and "adult" in addition) "is certain" to rebel against the roles assigned to her by the psychiatrist and "revert in some measure to her previous symptoms."

I find it disturbing that nowhere in this article is any mention made of the psychiatrist's viewing the "patient" or her husband as real human beings. They seem, rather, to be merely puppets whose strings the psychiatrist manipulates in order to move them toward fulfilling roles in a male-dominated nuclear-family drama, which Dr. Houck appears to take for granted as being the desirable end toward which they should strive. Such a state of affairs may or may not be right for any given married couple (after all, there are many other options open to them, either as a couple or as separate individuals), but that should be *their* decision to make, not the psychiatrist's.

Incidentally, I am both a psychiatrist and a male.

HAROLD ALTMAN, M.D.
St. Louis, Mo.

Dr. Houck Replies

SIR: The problem with terms such as "chauvinistic," "manipulative," "dominant," and "submissive" is that they are subject to different interpretations by different people. So, for that matter, is the idea of playing God. Certainly, almost any clinical discussion of a syndrome that mainly involves women is likely to be considered "chauvinistic" by some readers.

There may, indeed, be valid differences of opinion about whether the method of treatment I have outlined is appropriate. But Dr. Altman, in his concern about my "chauvinism," has introduced an idea that was not, in fact, included in my article. Nowhere in the article is there a statement that the patient "is certain to *rebel* [italics mine] against the roles assigned to her by the psychiatrist and revert in some measure to her previous symptoms." My statement was: "In the face of her best resolutions, she is certain to find the stresses of home and family ex-

tremely difficult. When that occurs, she is certain to revert in some measure to her previous symptoms."

Finally, Dr. Altman takes exception to my repeated use of the word "patient," objecting that I have not portrayed the patient or her husband as real human beings. If that is a fair interpretation, then I regret it deeply. The patient is, after all, the ultimate focus of all of medicine and always has been. This fact, it seems to me, is implicit in virtually all medicine, and I am not convinced that one needs to stipulate it.

Treatment for Tardive Dyskinesia

SIR: In the Letter to the Editor "Tardive Dyskinesia and the Rabbit Syndrome During Wakefulness and Sleep" (December 1972 issue) only one line mentions a potential treatment for this iatrogenic syndrome, which is observed more and more frequently among patients who have been exposed to unremitting chemotherapy for years. Can more detailed information be supplied, including the value and dosage of rauwolfia?

Testing for Mental Retardation: Comments on Standard Deviations

SIR: This letter is in reference to the article "Comments on the *ICD* Classification of Mental Retardation" by Dr. Joseph Wortis (May 1972 supplement).

In that article Dr. Wortis wrote:

> A test constructed in such a way will inevitably disclose that a minimum of 15 percent of the population utilized (i.e., IQs two standard deviations from the mean) is mentally retarded. . . . The . . . horn of the dilemma is this: If the test is restandardized and is thus adapted to a foreign nation, under the assumption that the intelligence of that nation's populace is normally distributed, one will again find that about 15 percent of the population is mentally retarded. . . .

Such statements disclose the author's ignorance of psychological testing and of elementary statistics. In any normal distribution only 2.2 percent of all cases are two standard deviations below the mean. Hence, if mental retardation is operationally defined as performance two standard deviations below the mean on an intelligence test, then only 2.2 percent of those in any normally distributed population will be labeled as retarded.

David Wechsler has defined mental defectives as those scoring two standard deviations or more below the mean; he concluded, therefore, that only 2.2 percent of any population should be labeled as defective or retarded.

RICHARD H. INGWELL, PH.D.
Indianapolis, Ind.

Dr. Wortis Replies

SIR: Dr. Ingwell is quite right; the first sentence he quotes does contain an unfortunate error. The sentence should read "one or more standard deviations." This error will not be found in the original version of the article (1); it was due, not to ignorance, but to an incomplete interpolation of the standard deviation when proofs were returned. The second sentence, which, unfortunately, Dr. Ingwell did not cite completely (in scientific controversy it is not good practice to quote only half of an adversary's sentence), clarifies the issue. The completed sentence reads ". . . about 15 percent of the population is mentally retarded, since a standardized test must yield roughly that percentage *one or more* standard deviations from the mean" (italics added).

The *International Classification of Diseases*, "A Manual on Terminology and Classification in Mental Retardation" of the American Association on Mental Deficiency, and the APA *Diagnostic and Statistical Manual of Mental Disorders*, second edition (*DSM-II*) all accept IQs of one or more standard deviations below the mean as criteria for mental deficiency. *DSM-II* defines borderline mental retardation as IQs from 68 to 85.

On a normal distribution curve one standard deviation below the mean would mean an IQ below 84 for the Stanford-Binet test; in a random population this should implicate 15.87 percent of the population. Two standard deviations below the mean would bring us to IQs below 69 and would reduce the number of retardates to 2.28 percent of the population.

Since the cutoff point is arbitrary, Dr. Ingwell can define mental retardation at any point he pleases, but widespread current practice puts it at an IQ of 83.

Brooklyn, N.Y.

The Crisis of Financing Residency Training in Psychiatry: A Diagnosis

SIR: An atmosphere of impending or actual crisis in federal support for psychiatric residency training has developed recently Initially this crisis took the form of no new additional funds. More recently, there have been threats from the federal government to decrease financial support for medical student and residency training. Following World War II, as a result of recognition of the psychiatric manpower shortage, a program of financial support for psychiatric education was started. This program fostered the development of departments of psychiatry and expanded training programs where they had not existed previously and changed the locus of psychiatric training from state or private mental hospitals to a general hospital and outpatient base. Further, these departments became the site of a great deal of clinical service and research into complicated biologic, social, and psychologic factors in the mental health field.

In the early 1960s, tensions began to appear between these departments and the National Institute of Mental Health. The earlier stimulus of manpower shortages had somewhat dissipated, and psychiatry gradually moved from being one of the smallest medical disciplines to becoming the third largest. As a result, individuals at planning levels in the federal government began to question whether residency training should continue to be supported by federal funds. Further, it became the common belief that most psychiatrists spent most of their time in private fee-for-service activities; thus it became difficult from a public policy viewpoint to support educational experiences that led to

high incomes and in which services were not delivered to the areas of highest need. In reality, psychiatrists probably spend more time than any other major medical discipline in public service.

The adversaries in this controversy were, on the one hand, the bulk of university leaders in psychiatry, and on the other, smaller segments of that group and the policy setters at NIMH and HEW. The leadership in university departments maintained that they had more experience in educating and that the programs which had been developed were of high quality. Many of these programs were based on parts of human service delivery systems which could be controlled, so that trainees would receive a carefully regulated amount of clinical activity and responsibility and thus might spend sufficient time in clinical service, in learning about psychotherapy, in a didactic curriculum, and in learning about the basic sciences that underlie our understanding of mental health and illness. The psychiatric educators who took this position were, to a considerable degree, those who were opposed to or had limited involvement in community mental health centers.

Other psychiatric educators and public policy leaders took the position that high-quality psychiatric education should be delivered mainly in high-quality comprehensive service systems. The trainee needs exposure to the successes and difficulties of such a service system. If the system is not integrated and comprehensive, then the trainee's experience will be as fragmented as the services within the system.

In the last two years several other forces have joined the argument. In some instances they are exploiting the disagreement for their own objectives. The proposal of the Administration to begin phasing out federal support for residency training in psychiatry, first in fiscal year 1972 and then in fiscal year 1973, were examples. In order to make its case a logical and realistic one it used the sketchy and questionable evidence accumulated by the group supporting the development of community mental health centers.

In a complicated political arena the Congress restored these recommended cuts. Thus, the funding of psychiatric training has become a political issue in which, on the national level, more Democrats support mental health services and training and more Republicans oppose them. Such partisanship should not be a part of the decisions surrounding training and the delivery of services to human beings.

The financing of medical education will probably require rethinking for both the medical student and residency levels. The financing of psychiatric education should occur in this larger context. Some support for training could come from fees derived from service. That, however, cannot and should not be the only or prime basis for supporting psychiatric education. The dangers in such an outcome include too intense a focus on inpatient care, too much involvement with service, too little attention to the knowledge underlying psychiatric activity, and too little emphasis on complex biologic, social, and psychologic understanding. The balance of financial support between local and national sources must also be reviewed and reevaluated. Possible outcomes of such review are: 1) a loan plan, with repayment stipulations; 2) some financing through clinical service; 3) local, state, and some national support based on public need; 4) more efficient training at lower cost; and 5) the channeling of service monies appropriated for current social problems into relevant educational activities that have a mental health component (a current example is drug abuse).

The dilemma that confronts us is whether we continue this nonsensical conflict between adversaries while we destroy the public support and financial base of our educational programs, and ultimately, our profession, or whether we begin once more to plan and to develop conjointly balanced educational programs that meet some of the requirements of each of the opposing groups.

BOOK REVIEWS

Depression: Comparative Studies of Normal, Neurotic, and Psychotic Conditions, *by Edith Jacobson, M.D. New York, International Universities Press, 1972, 336 pp., $13.50.*

Early in her psychoanalytic career, Edith Jacobson became deeply involved in the most challenging clinical problems: those of the narcissistic states—borderline and psychotic conditions. Following the lead of Karl Abraham, who had had remarkable success in treating manic-depressives, she became engaged in analyzing patients whom few analysts dared to approach, even with psychoanalytically oriented psychotherapy. At this early period ego psychology, and most particularly its technical applications, was in its infancy. As a matter of fact, it is only within the last decade that it has really begun to come into its own. Its enormously fruitful findings, especially the discoveries of early ego developmental phases, have only within the past five years begun to reveal their effectiveness in applications to technique. The work of Otto Kernberg on borderline states, singled out by Jacobson for its outstanding quality, is an excellent example of such avant-garde significance.

Thus this grand old lady of psychoanalysis may rightly be described as a true innovator in both theory and practice. To read the succinct accounts of the innumerable clinical cases that illustrate her hypotheses in the most subtly differentiated way is a most rewarding experience. Here is the master psychoanalyst. Again and again she traces her patients' dynamic and structural constellations down to their infantile sources, correlating them boldly and convincingly with their presenting conditions and relationships to current realities. What she does not enunciate is what we all know—that this would not be possible without the extraordinary charm and maturity of her personality—warm, giving, always reflecting a joie de vivre and an intellectual passion that have not abated with the years.

But this is not a book for the uninitiated. The theoretical formulations are presented in a torrential flood, the ideas literally leapfrogging over each other in their eagerness to be said. It requires a grasp of advanced psychoanalytic theory and often much rereading to distill out the clarifications that the author has so signally contributed to affect theory, the vexing problem of moods, the nature of the primitive ego defenses that characterize borderlines and psychotics, and the kaleidoscope of psychic phenomena surrounding the nature of depressive states.

With respect to her general approach, it is noteworthy that here is one analyst who does not fail to take into account the presence of constitutional, hereditary, and neurophysiological factors in the affective states. Thus, after exhausting all psychogenic considerations in a particular psychotic patient, she was able to reach the conclusion that sudden emergences from long-standing periods of depression, and indeed from apparently deeply regressed schizophrenic states, could be explained only on an organic basis. She deplores the lack of interest in somatic research problems among numerous psychoanalysts as much as the psychiatric and psychoanalytic ignorance of many neurophysiologists, who conduct research studies in psychotic disorders that require "careful differential diagnostic considerations."

In the field of affect theory, which is as yet in an unsatisfactory state from a psychoanalytic point of view, Dr. Jacobson brings in new dimensions of timing, rhythm, and suddenness, discussing them not merely phenomenologically, but from the genetic viewpoint. Chapter 2, which presents direct observational data on smiling and laughter in infants and young children, is most illuminating in this respect. I would have wished that the author had touched upon the relationships between affect and cognition, especially their genesis, but this problem as yet remains largely unexplored.

It is impossible to do justice to the section on depression in a brief review. It must suffice to say that Jacobson alludes to Freud's second anxiety theory, his new ideas regarding the role of aggression, the beginning of structural thinking, and the development of ego psychology as forces in motivating investigations into the problems of depression. However, she deplores the blurring of strict lines between neuroses, borderline states, and psychoses and between the different types of psychotic disorders, which she feels have resulted from overemphasis on purely psychogenetic factors. It is her firm conviction that the psychology of the psychoses can ultimately be understood only by psychoanalytic studies directed to "the individually different, specific psychogenetic factors; the specific structure and nature of the conscious and unconscious conflicts; the characteristic affective and mood conditions; the specific defenses and restitution mechanisms in each group of psychosis."

I could not agree more heartily with this emphasis on specificity. To it, the author has contributed, among other things, an understanding of the interplay between self and object representations, which furnishes a most effective tool in differentiating between specific disorders. I am sure her ever-fertile mind will continue to expand psychoanalytic theory in similar directions in years to come.

NATHANIEL ROSS, M.D.
New York, N.Y.

Profession of Medicine: A Study of the Sociology of Applied Knowledge, *4th printing, by Eliot Freidson, Ph.D. New York, Dodd, Mead & Co., 1972, 382 pp., no price listed.*

If asked what makes them professionals, most doctors would probably reply that their professionalism lies not only in their special knowledge but also, and possibly even more importantly, in a certain set of attitudes including a dedicated commitment to their work and a sense of responsibility toward their patients. Eliot Freidson, however, in *Profession of Medicine*, rejects this definition as being difficult to operationalize and certainly unvalidated. He prefers to define a profession in structural terms as an occupation that has achieved a great deal of autonomy in controlling not only the technological but also to a large extent the social and economic aspects of its work. By virtue of public acceptance of its competency in performing the highly valued service of restoring ill people to health, medicine has become the preeminent profession. Society, however, bestows such autonomy on a profession in return for an implicit promise that the profession will keep order in its own house, that is, that it will maintain effective standards of performance by its members.

Having been vested with more or less exclusive jurisdiction over illness, the medical profession finds itself in a very powerful position, which can be and is used for purposes of social control. This is so because illness, in addition to its biophysical determinants, is also an important social phenomenon; and it is the doctor who, by his diagnosis, has the power to define certain individuals as ill and thus to place them in a category with significant responsibilities and privileges. Illness thus may be usefully considered as a form of social deviance, in our country probably the most important form. It differs from the other variety of social deviance, criminality, because ill people are not held to be responsible for their behavior, while criminals are. For instance, if doctors define certain aberrant behavior patterns as mental illness, alcoholism, or drug addiction, these conditions become illnesses subject to treatment rather than punishment.

Dr. Freidson makes a fundamental distinction between "the pure knowledge and theory of the profession which is largely confined to codified science and the knowledge guiding the professional's application of that science to problems of mankind." That is, the manner in which the medical professional applies his scientifically acquired knowledge to the practical problems of his practice is not in the same category as that scientific knowledge, and it is very much subject to individual idiosyncrasy and, even more, to economic and guild considerations.

The vaunted expertise of the profession is often little more than disguised self-interest when applied to the conditions of its work and to the control of incompetent and unethical performance in its ranks. Its claims to infallibility differ from those of labor unions only by being more sanctimonious. This flaw can and should be improved by much more rigorous self-scrutiny, but it cannot be entirely cured by the profession alone, no matter how conscientiously it tries, because the very autonomy that defines medicine as a profession renders it therefore incapable of governing itself in the public interest. Dr. Freidson says that he does not want to abolish this autonomy, only to temper it, but the thrust of his book certainly is in the direction of a drastic modification of the power of the medical profession to regulate itself.

In addition to the main argument of the book as summarized here, there is much more in it to interest, stimulate, and very probably to disturb physicians and provoke them to disagreement. Yet, as stated in the introduction, the profession of sociology has something to say to the profession of medicine. Doctors certainly ought to pay more attention to what sociologists can tell them about their profession than they have in the past. It is possible that their receptivity to sociological criticism will be increased as increased governmental and other forms of third-party scrutiny breach the bastions of their professional autonomy.

The discussion of illness as social deviance, alluded to earlier in this review, will be of particular interest to psychiatrists since it offers another way of looking at the no-holds-barred struggle between advocates of the medical model of psychiatric illness and those who discard such a model entirely. For if from an operational viewpoint illness is in a sense created by the diagnosing activity of physicians, and if all illness (not only that treated by psychiatrists) is a social as well as a biophysical phenomenon, then the absence or relative unimportance of biophysical factors alone will not be sufficient to remove conditions so diagnosed from the category of illness. As long as our society accepts any conditions that doctors diagnose and treat as illness, then the patients of medical doctors specializing in psychiatry will also be considered to be ill.

PAUL CHODOFF, M.D.
Washington, D.C.

The Mind of Adolf Hitler: The Secret Wartime Report, *by Walter C. Langer. New York, Basic Books, 1972, 263 pp., $10.*

This book contains part of the wartime psychological analysis of Adolf Hitler done in 1943 for the Office of Strategic Services, the forerunner of the Central Intelligence Agency. It is an important and timely volume, appearing as it does at a time of increasing interest in psychohistory, and given the circumstances—the absence of the patient, the state of the art in 1943, and the wartime overreactions against Hitler—the study is an outstanding achievement.

The book can be divided into two parts. The first half summarizes and reviews the then available information on the German dictator. This is by far the best part of the book; it reveals the amazing amount of facts known to the Allies about their enemy, and it properly presents and interprets them with the caution this kind of information calls for.

The second half is taken up with the "psychological analysis and reconstruction" of Hitler's character. It is here that most of the book's weaknesses are to be found. The author's professed good intentions notwithstanding, the analysis often degenerates into risky and implausible generalizations based on highly dubious evidence or, worse still, on no evidence at all but on ex post facto tailoring of evidence. For instance, he states, "Not a single patient manifesting Hitler's character traits has grown up in . . . a well-ordered and peaceful home environment." Therefore his early home life *must* have been disruptive, and the scanty evidence available is made to fit a Procrustean bed. In addition, the author states, "As a child he *must* [italics mine] have discovered his parents during intercourse." This statement is repeated so many times that the author finally believes it himself and builds a large part of his theoretical formulations on it.

On the whole the analysis itself greatly suffers from overzealous adherence to some aspects of orthodox psychoanalytic theory, or, to put it differently, it reflects some of the shortcomings of the state of the art in the early 1940s.

Moreover, in view of the author's stated purpose to publish the study "as an historical document," I find two aspects of the book objectionable. First, Langer fails to mention the names of his three collaborators—Henry A. Murray, Ernst Kris, and Bertram D. Lewin. This is especially objectionable in view of the fact that one of them (Kris) is a landmark name. Secondly, comparison with the original text shows that entire passages have not only been edited, but added to. This is especially regrettable in the section on Hitler's "Probable Behavior in the Future," since the original predictions were quite astute.

Regardless of its weaknesses, however, this book will take its place in the history of the profession as the first serious and comprehensive, expert study of a political figure without benefit of direct examination—a role that the profession will be asked to assume, I believe, with increasing frequency. An updated study, making use of the data that have become available since the end of the war, would be most desirable.

IVAN FRAS, M.D.
Binghamton, N.Y.

Short-Term Psychotherapy and Emotional Crisis, *by Peter E. Sifneos. Cambridge, Mass., Harvard University Press, 1972, 295 pp., $10.*

Brief psychotherapy is a genus with many species, and one regretful tendency of the proliferating literature in the area has been a failure to differentiate among the various forms that psychotherapy of short duration can take. Dr. Sifneos carefully

avoids that pitfall, however, by concretely defining the two types of brief psychotherapy with which he deals.

Anxiety-suppressive psychotherapy ("crisis support") refers to the use of reassurance, environmental manipulation, hospitalization, or medication to help the patient through an acute crisis. Maximal use of social agencies and involvement of members of the family help to decrease or eliminate as quickly as possible the external factors responsible for the crisis. Even though it usually lasts no more than two months, crisis support tends to produce marked symptom relief and often teaches the patient to avoid the situations that brought him to treatment in the first place.

In contrast to crisis support, crisis intervention (anxiety-provoking therapy) seeks to produce dynamic changes in the patient by challenging his maladaptive reactions to crisis before they become fixed into neurotic symptoms. The therapist's role is that of an "unemotionally involved teacher" who concentrates on current unresolved conflicts. He deliberately avoids dealing with more primitive character traits, since they are unlikely to respond to short-term treatment.

In addition to describing the treatment, the author gives specific criteria for the selection of patients, based on his experience over a 14-year period as Director of the Psychiatry Clinic of Massachusetts General Hospital. He also provides an evaluation of treatment results, based on follow-up interviews. While many patients had only moderate symptom relief, they were less bothered by their symptoms or better able to live with them. The majority of the patients felt that therapy had taught them new ways of dealing with problems. Most striking was an increase in self-esteem that paralleled patients' decrease in self-preoccupation and self-centeredness.

The writing in this book is simple, straightforward, and direct. Clinical material is abundant; it consists not of the usual overpolished vignettes but of extensive excerpts from recordings of sessions. The reader quickly gets the feel of the process of therapy as he sees how concepts and theories are tested in practice. The book can be recommended to supervisors and teachers as a possible introductory text on brief treatment techniques.

ROBERT J. CAMPBELL, M.D.
New York, N.Y.

The Psychology of Death, *by Robert Kastenbaum and Ruth Aisenberg. New York, Springer Publishing Co., 1972, 485 pp., $11.95.*

Here is a truly useful book that covers a wide range of concepts, previous writing, and clinical problems surrounding the fact of death. The authors direct their substantial and well-organized efforts toward readers involved in research having to do with death and clinicians involved as counselors, as well as toward those who have a scholarly interest in this subject. A prime quality of the book is its meticulous, detailed summaries of a great number of research studies.

The authors employ a developmental focus throughout, citing research on death fears, ideas and concerns about various kinds of serious illness in children, and the reaction of children of various ages to death experiences. Both developmental stages and developmental issues are amply illustrated by summaries of the literature and the authors' case material and research data.

A section on psychological factors in prolonging or curtailing life is of particular interest. In addition, there are sections on suicide, murder, and illness as they are related to concerns about death, as well as several detailed, well-written sections dealing with comparative historical views of death. The authors' unusual thoroughness gives the reader a great amount of information on such esoteric concepts as premature burial and suspended animation.

As a critical view of findings and concepts in regard to death, this volume is without parallel. It offers a great deal to the teacher, the clinical student of death, and those interested in cultural, philosophic, and anthropological views of death.

Many sections of the book open with questions, many of which will parallel those of the reader and will therefore offer a stimulus to greater involvement in the book. The last section constitutes an excellent epitaph for the volume as well as a spur to the reader: "If an additional measure of care could be given to making the world a better place in which to die, would this not also make our world a better place in which to live?"

Freud and the Americans: The Beginnings of Psychoanalysis in the United States, 1876–1917, *by Nathan G. Hale, Jr., Ph.D. New York, Oxford University Press, 1971, 558 pp., $15.*

The author, a teacher of history at the University of California at Riverside, apparently has written previously about psychologists, psychiatrists, and emotional illness. His acknowledgments indicate that he has interrogated many professionals and read their books as sources for his information. He not only discusses Freud but also describes in some detail the psychologists and psychiatrists of the period and their kinds of psychiatry before, during, and after Freud's visit to the United States in 1909. The book therefore is an overview of psychiatric history and will be useful for the student and for the beginner, who is rarely taught the roots of what is current.

Nevertheless, the author's attempt to cover his subject under various headings has led to repetitions, and what he has learned from his sources are the formal aspects of psychiatry and psychoanalysis. What is personal and describes Freud as a human being whose personality influenced American psychiatry even more is buried in the Freud archives, not to be opened for many years.

For example, Freud's hatreds included Americans who took to fads inconsistently. Why could he have said that he wished the land had not been discovered? He told me that when Jung reported to him that minimizing the theory of the sex instincts helped Americans to accept psychoanalytic theory, he (Freud) said that psychoanalysis would be destroyed. Many years later he still resented the incident at Putnam's camp in the Adirondacks in 1909 when, while he was writhing on the ground with intestinal cramps, Putnam said, "That's too bad," and walked away.

We are not told about the profound influence on American psychoanalysis of A.A. Brill's abrasive effect on others and of the disasters resulting from his poor translation of Freud's early works. One could go on and on with personality details of great importance for the current state of the art.

Nevertheless, the author does indicate the psychiatric field that formed the ground into which Freud planted the seeds of psychoanalysis. It included a somatic bias inherited from the German school of Kraepelin, Nissl, and Alzheimer, the disguised humanism of Weir Mitchell, and the mystical wave of Bishop Emmanual's movement, whose treatment, my father said at the time, was "not fit for dogs." The puritanical surface morality even led to the original state hospital superintendents designing "moral treatment." The underlying and undercover sexual drives only needed an excuse to break out, based on mis-

interpretation of Freud's theories. It is sad that the American optimism for therapeutic results from psychoanalysis, which was not shared by Freud, was later crushed. Certainly the cathartic method of those early days, before the development of ego psychology and the analysis of resistance, was not the answer to American hopes, and new fads have since been developed.

I will not discuss the author's application of Thomas Kuhn's paradigmatic model of scientific revolutions to psychoanalysis; that has been the subject of several debates in the literature (1). I can only state that the author tries and thus becomes more of a sociologist than a historian, and less effective.

In sum, the book is interesting; future volumes will fill out later periods of Freud's life with the Americans despite his antagonistic view of them. It is to be hoped that subsequent works will be shorter and sharper and will contain more of the essence of psychology.

The Will To Be Human, *by Silvano Arieti, M.D. New York, Quadrangle Books, 1972, 272 pp., $8.95.*

The author is Professor of Clinical Psychiatry and Training Analyst at the New York Medical College and is a member of the faculty at the William Alanson White Institute. His message is an alternative to the behaviorist approach to the role of the will in the human condition, an affirmation of man's humanity, and an encouragement to him to assume his own direction.

Man's will, the capacity to make and implement choices, has been battered and broken by his rearing, his so-called education, social unrest, unremitting wars, depression, shabby ethics, and the erosion of moral authority in Western culture. Often enough he becomes an automaton, responding to his "fate" in the manner depicted in Vachel Lindsay's lilting lines:

> Not that they starve, but starve so dreamlessly;
> Not that they sow, but that they seldom reap;
> Not that they serve, but have no gods to serve;
> Not that they die, but that they die like sheep.

But this is not to mistake the fact for the possibility. Man contains within his skull a most wondrous structure, and it is a continuing mystery why, with it, he is so often unable to improvise. He learns how to perform a task well enough, and when times change and the routine is no longer pertinent he collapses into hopelessness. For this he has a network of more than ten billion nerve cells? Little wonder that the behaviorists regard him in the main as a reacting primate.

Arieti explores the evidence that will exists and that if will has been relinquished it can be resurrected. He traces the evidence for the will from birth to death and the effect of many modifiers upon it. Will develops as the most specifically human characteristic, but it is achieved only by constant striving. Arieti says that although inviolable laws govern the cosmos, the will of man is unpredictable. So if free will exists, it is required of man to carry the burden of responsibility. To the extent that he is free, he is unpredictable and, accordingly, must assume responsibility. Perhaps it is this very burden which causes him to relinquish will so readily along with responsibility.

Behavior does not exist in pure culture. Man is never completely free, and to the extent that he is not, he is to some extent unauthentic and unresponsible, with circumstances likely to blunt his potential creativity. The author's intent is to sketch the way toward autonomy, common good, communion, and peace. He has written a humane book of considerable insight. Even though the sociohistorical times are inhumane, he sees in man the will to be human. We are not necessarily creatures of our environment and our unconscious, since we retain a certain direction of our affairs even in unfavorable circumstances. It is toward enlarging this direction that Arieti explores the potential of the will.

This book is a thoughtful exposition on the role of the will in human affairs and, accordingly, contains something of value for every thinking person.

The Mental Hospital in the Psychiatric Service: A Case-Register Study, *by J.A. Baldwin, M.A., M.D. New York, Oxford University Press, 1971, 333 pp., $18.*

This book is the brilliant description of Dr. Baldwin's odyssey during the years 1961 to 1968 as Scottish Hospital Endowments Research Trust Fellow in the Department of Mental Health of the University of Aberdeen. He undertook to examine the place of the mental hospital in the contemporary medical and social scene. He sought to understand the nature of the challenge to the 200-year-old dominant and monopolistic position of the mental hospital as the social, legal, and medical embodiment of psychiatric care. Dr. Baldwin studied the relationship of the mental hospital with the service and community environment from which it draws, and to which it returns, its patients. His methodology is best described in his own words (p. 2):

> The objective of the programme of research reported in this book was to design and develop an information system capable of supplying the most obvious deficiencies in data, to use it to provide at least preliminary answers to some of the outstanding planning problems and to evolve practical tools for evaluating management and planning decisions.
>
> The central methodology of the inquiry is epidemiological. The method of record linkage was used to construct a cumulative file, or register, of longitudinal records based on the person as the unit of record. This approach was applied to a population defined both geographically and in terms of an administratively integrated system of mental health services in the north-east of Scotland.

Heeding to the epidemiological line, Dr. Baldwin asks: What observable effects on morbidity result from the actual activities of clinical staff, patients, and administrators within the mental hospital subsystem? He gives an affirmative reply to the question of whether the scientific method rather than the value judgment can be used for the planning and management of mental health services, but cautions, "In practice, in the present state of psychiatry, adequate objective measures are virtually impossible to attain" (p. 3).

The first chapter is an elegant description of the historical evolution of the mental hospital as an institution in its own right. This is followed by a consideration of the requirements

for planning mental health services. Annual net change, cohort models, the pattern and determinants of demand, and models of service function are reviewed, to be discussed in greater detail in later chapters. Chapter 3 gives an excellent review of mental health information systems, with particular reference to the psychiatric case register. Subsequent chapters deal with the dynamics of patient flow, models of mental hospital function, the mental hospital within the context of the service system, and community demand.

Dr. Baldwin draws a number of interesting and, I believe, valid conclusions from his studies. For example, he points out that the attrition of the standing population of the mental hospital is like the decay of radioactivity (p. 178): "Results of application to north-east Scottish mental hospitals show a curvilinear outcome with a relatively short period required to halve the population but a very long one to eliminate it." His cohort studies lead him to believe that the aged senile woman will replace the young male schizophrenic as the main problem for the mental hospitals of the future.

Although the book is liberally supplied with charts, graphs, and some statistical formulas that were beyond my understanding, there is a very satisfactory appendix describing the characteristics of the region containing Aberdeen, Kincardine, Banff, and Moray and the island counties of Orkney and Zetland. An early description of conditions in the Royal Cornhill Hospital, opened in 1800, noted: "On Shrove Tuesday 1873 each patient had brose with a ring in it 'supposed to bring good fortune to its finder.' " Brose, I discovered, is porridge hastily made by pouring boiling water or sometimes milk, beef broth, or the like on meal and stirring them together. Plus ça change, plus c'est la même chose.

Dr. Baldwin's book is a significant contribution to the rational planning of mental health services. It brings a clear understanding of the relationship of the mental hospital to the extramural services. The book is an endorsement of the comprehensive community mental health center and its system of services, and it lends powerful support to current efforts by New York State's Department of Mental Hygiene to fully integrate state hospital and community services. I believe that Dr. Baldwin's studies will find wide acceptance and interest among planners and administrators of mental health services.

Syosset, N.Y.

Infantile Autism: Concepts, Characteristics and Treatment, *edited by Michael Rutter, M.D., D.P.M. Baltimore, Williams & Wilkins Co. (exclusive U.S. agents), 1972, 319 pp., $13.75.*

This book, the product of a CIBA Foundation symposium chaired by Leon Eisenberg under the auspices of the London Institute for Research Into Mental Retardation, will be of value to those who wish to place current knowledge about infantile autism in historical perspective.

Recognizing the frequent misuse of the diagnosis, the contributors agree upon the following essential characteristics of infantile autism:

1. It begins during the first two and one-half years of life;
2. It involves a defect in the development of social relationships, a global impairment of language, and rigid or ritualistic patterns of behavior;
3. It is not related to adult schizophrenia;
4. It is not primarily caused by psychogenic influences; and
5. It probably is due to multiple cognitive, perceptual, and language deficits. Although the influence of parenting is recognized, the overwhelming evidence stresses etiological deficiencies in the equipment of the child.

The discussions of classification differentiate childhood psychoses by age of onset, distinguishing three forms: infantile autism; disintegrative or symbiotic psychosis, with onset during early childhood; and schizophrenia, with onset during later childhood and adolescence.

Chapters on the etiology of infantile autism by Ornitz and DeMeyer agree upon the presence of a central integration deficit between sensory input and motor output. They hold the view that the autistic child does not process data efficiently because he *can't*, rather than because he *won't*. They also introduce an element of prognostic hope from maturation of the central nervous system alone, highlighting the need to protect the developing autistic child from the stultifying effects of isolation and understimulation. As an interesting sidelight, Rutter notes that one-third of his series of autistic children developed grand mal seizures prior to their adult years.

Studies of language show that the "echo-box" auditory memory of the autistic child is not impaired; however, "nonsense" is remembered as readily as "sense." Autistic children have language difficulties similar to those seen in aphasic children; however, their impairment spreads beyond speech to other forms of symbolism, such as signs and gestures.

A significant contribution to the treatment of infantile autism is made by Schopler and Reichler through their recognition that parents hold the keys to change in their child and that parents should be involved not only in the direct management of their children but also in the political arena, to press for needed services in their communities. The discussions of behavioral modification programs with autistic children confirm a generally disappointing outcome. More comprehensive educational approaches are recognized, and several chapters are devoted to speech therapy programs.

Omitted in this volume are studies of motivational factors in the autistic child and psychodynamically oriented milieu programs, particularly as they relate to supporting parents, educators, and child care personnel in their frustrating, painstaking, and prolonged work with autistic children.

Eisenberg concludes the symposium by noting recurring fads in the treatment of autistic children. He points out that if operant conditioning methods have done nothing more than inspire hope of changing autistic children, they will have made no small contribution. He appropriately calls attention to unethical promises made by those who involve parents, relatives, and friends in intensive training programs for the autistic child. When the inevitable limited response occurs, it is often attributed to inadequate application of the method, thus only augmenting parents' guilt and obscuring the fact that no simple, universally effective treatment method has been found for infantile autism. The treatment of choice remains coordinated, interdisciplinary management of the autistic child's life, beginning with his family, moving through the development of language and social relationships, and continuing through community-based specialized educational programs.

Religion and Bereavement: Counsel for the Physician, Advice for the Bereaved, Thoughts for the Clergyman, *edited by Dr. Austin H. Kutscher and Lillian G. Kutscher. New York, Health Sciences Publishing Corp., 1972, 224 pp., $12.50.*

I am afraid that the editors of this book strove to accomplish

too much, with the sad result that they achieved too little. Despite the threefold subtitle that specifies three large groups of potential audiences (and consumers), I find that the book consists primarily of musings by clergymen on death and bereavement. These musings are very uneven in quality, length, and thoroughness. Some read like sermonettes. Others are aphoristic paragraphs without clear connections. Here and there is some poetry. Sprinkled throughout are repeated efforts by Edgar Jackson to teach some basic ideas about grief and grief-work, but these are so fragmented and simplified that one can hardly imagine that his ministerial colleagues or physicians will feel instructed by such scattered teaching endeavors.

When I opened the book and glanced at its table of contents I hoped that I would find a comprehensive desk-reference work on death and bereavement with first-class resource material, for I think this is needed and I expected the president of the Foundation of Thanatology to be interested in producing it, for the use of both clergymen and physicians. Instead, the participating clergymen have primarily produced some edifying meanderings, from whose tone and conceptual level I surmise that they had "the bereaved in general" (whoever they are) in mind.

There is much talk about the virtues of faith when one is bereaved, plus some small efforts to correct mistaken conclusions that one might draw from some religious propositions. For the disaffiliated, disbelievers, or unbelievers there is practically nothing. But if I were a faithful Jew or Christian, and bereft, I would like to have direct recourse to the primary sources of my faith for consolation, courage, or instruction: the great classical prayers, the Psalms, the liturgical treasures of my denomination. Why settle for these musings, albeit they are from men of goodwill, when most faith groups and denominations have superior material to offer? And why settle for small instructional fragments when there are good books on understanding and managing grief?

The major headings in the table of contents are appealing. They consist of A) Understanding Grief, B) Religious Approaches to Death and Mourning, C) Dying, D) Coping with Grief, E) Practical Ministry and Care, and F) Approaches by the Ministry to Recovery from Bereavement. There is also a short (two-page) anthology of selected readings and poems and a list of music selections that contains such strange bedfellows as Wagner's "Gotterdammerung" and Mahler's "Kindertotenlieder." Section F contains the raw data of a survey that the editors conducted among clergymen, widows, and widowers, but they make no attempt to analyze the data or draw conclusions from them.

Although I like the idea of such a work as mapped out in the table of contents, this particular book does not deliver it. I imagine that most of the collaborators themselves will feel dissatisfied with it.

OFFICIAL ACTIONS

Fall Committee Meetings

Following is a summary of the proceedings of the fall committee meetings of the American Psychiatric Association, which were held in Washington, D.C., in October 1972.

The Council on Medical Education and Career Development

ALBERT J. SILVERMAN, M.D., CHAIRMAN

THE MEETING of the Council on Medical Education and Career Development began as requested with extensive discussion of the future of the component parts of the Council. A discussion was also initiated on a proposed reorganization of the Council along more functional lines. This discussion will be continued during the Council's early spring meeting, and the members anticipate presenting a plan for proposed reorganization to the Reference Committee shortly afterward. The Council also made certain recommendations relating to its component parts that will be noted in relationship to its specific reports.

The Council received with thanks a report on the forthcoming Medical Education Conference from Dr. Ewald Busse. The Council recommended that psychopharmacological education be explored during the conference and also recommended liaison with the American College of Neuropsychopharmacology to achieve this end.

The Council received the request that the wording of the APA Membership Certificate be changed to read: "Qualified Psychiatrist." The Council recommended that since a method of certification in psychiatry already exists and since APA is not a qualifying organization, the proposed change not be approved.

The Council considered the request that a *Task Force on Audiovisual Definitions in Psychiatry* be established. While agreeing in principle that the project had a great deal of merit, the Council recognized that the problems of standardization are considerable and recommended that this proposal be considered in the Council on Research with the Task Force on Nomenclature and Statistics and Committee on Public Information acting as liaisons.

The Council then considered the matter of licensure and certification of specialists as well as that of relicensure and recertification. In view of the fact that an examination route already exists to certify that a person is qualified as a psychiatrist, the Council was opposed to setting up another route. The Council approved the following statement and recommended its adoption as policy by APA:

> Council is in favor of relicensure and recertification of the psychiatrist provided there is full equity and safeguards for the consumer and for the psychiatrist. The consumer would require protection with respect to the competency of the psychiatrist, his need for a psychiatrist, and the status of the patient/doctor relationship.
>
> The psychiatrist would need protection with respect to his right to continue to earn a livelihood. Relicensure and recertification would be meaningless unless there is some method of evaluating credits for continuing education and for the establishment of a national uniform examination that would *reliably* measure clinical competence.

The Council noted that the *Task Force on College Health*, James R. Raybin, M.D., chairman, did not meet. The Council received a position statement previously prepared by this task force and recommended that this position statement be adopted by APA. Since the task force has accomplished its work, the Council recommended that it be disbanded with thanks.

The Council noted that the *Commission on History*, Robert N. Butler, M.D., chairman, had delayed its meeting in order to meet with the Committee on Program later in October.

The report of the *Task Force on Training of Foreign Medical Graduates*, Milton H. Miller, M.D., chairman, was received with thanks. A grant application has been submitted to NIMH for a three-year demonstration program to begin in July 1973. A number of papers have been presented and are being published.

NIMH also proposed sponsorship of a series of programs devoted to the nature, value, and future of North American psychiatric training for Asian psychiatrists. Key Asian psychiatric educators will be guests at the annual meeting in Hawaii in order to participate in these discussions.

Subsequent to the decision of NIMH regarding the grant application, the task force (prior to its expiration in May 1973) will present a series of definitive recommendations regarding APA's role with regard to the foreign medical graduate. The Council approved an extra meeting of the task force, if necessary, to develop these recommendations.

The Council received with thanks the report of the *Committee on Psychiatry and Medical Practice*, Jacob Swartz, M.D., chairman. The colloquium held in San Diego in February

1972 drew 125 participants. The program was considered interesting, but the participants desired more extensive small-group discussions. In August 1972, the committee was invited by the Mental Health Committee of the American Academy of Family Physicians to a meeting in Denver in order to act as consultant for the Academy's NIMH Family Practice training grant and to join in planning for the 11th Colloquium on the Postgraduate Teaching of Psychiatry, which the two committees will cosponsor; the colloquium will be held in Charleston, S.C., in March 1973.

The Council accepted with thanks the report of the newly formed *Task Force on Continuing Education*, James Naiman, M.D., chairman. A recommendation dealing with Dr. Busse's suggestion regarding continuing education, periodic reexaminations, and APA membership was not considered sufficiently clear or precise for the Council's action. If the recommendation could be made clearer, the Council would discuss it at its early spring meeting.

The Council supported the recommendation that groups to instruct teachers be financed by APA in that NIMH refused to finance them; it did not support the recommendation that APA go on record as recommending to departments of psychiatry that they value the teaching of continuing education and that they demonstrate this in relationship to remuneration, promotion, etc.

Regarding the recommendation that APA charge the district branches with generating continuing education plans, the Council expressed the belief that the area council, in collaboration with a nearby medical education center, would be a better vehicle.

The Council also approved in principle the task force's recommendation that the curriculum in continuing education be divided into two parts: 1) basic knowledge required of every psychiatrist, and 2) courses dealing with a psychiatrist's particular area of expertise.

The Council also approved an extra meeting of this task force if necessary.

The report of the *Task Force on Drug Abuse and Drug Education*, Peter Bourne, M.D., chairman, was received with thanks. This task force is preparing an acute treatment manual for drug abuse emergencies in collaboration with the National Clearinghouse for Drug Abuse Information. This would be published and distributed by the National Clearinghouse and was expected to be ready in April 1973; it would include chapters on alcoholism. The Council recommended that this be endorsed as an official joint project between APA and the National Clearinghouse. Two members of the Council would review the completed manuscript, make recommendations to the entire Council, and, through it, to APA for its endorsement.

The Council noted a tentatively proposed moratorium on further federal expenditure in the field of drug abuse education through the mass media. The Council deferred any recommendation on this item until further information has been received.

The Council endorsed the recommendation that training in the field of drug abuse and alcoholism be required by all residency training programs, that some skill in this area be taught to others in the field of mental health, and that APA use its influence to require that the provision of such training be made a requirement in order for training programs to be accredited. The Council further suggested that this information be presented to the self-assessment examiners, to all those involved in continuing education, to the American Board of Psychiatry and Neurology (ABPN), and at the forthcoming conference on medical education.

The task force also responded to a request from the then Secretary of HEW, Elliot Richardson, that APA look at the possible establishment of a training model for leaders in the field of drug abuse. The task force decided to present a recommendation determining whether the guidelines established by the National Institute on Alcohol Abuse and Alcoholism for training in the field of alcoholism can be modified to fit the drug abuse field in general.

In considering the task force's concern about the fragmentation of APA effort in the area of drug abuse, the Council recommended the development of an Ad Hoc Coordinating Committee on Drug Abuse and Alcoholism, consisting of the chairmen of all components that deal with this problem.

The report of the *Task Force on School Consultation*, Sheldon D. Glass, M.D., chairman, was received with thanks. Its appointed task, the preparation of a monograph dealing with this area, was reported to be approximately 50 percent complete. Approval was given for telephone conference calls to facilitate this work; completion is anticipated for fall 1973.

The Council received the report of the *Commission on Manpower*, L. Douglas Lenkoski, M.D., chairman, with thanks. The report recommended that the commission be responsible for data collection, distribution, utilization and manpower operations, and that it exercise an advisory function in relation to the APA Division of Manpower Research and Development. The Council expressed the belief that the work of this commission is most important but recommended that since its operations do not fit into the framework of an educational and training council, the commission be transferred to another council such as Mental Health Services or Research and Development.

The commission also noted that AMA had not approved its request for corrective therapists to be placed on their list of officially approved allied health professionals. The commission has taken no action on the request of art therapists and mental health technologists to be accredited by AMA. The commission reported that in order to do so detailed surveys must be conducted, and staff assistance is essential. The Council decided to discuss this issue at its early spring meeting, in which it will have APA staff input.

The report of the *Committee on Medical Education*, Robert J. Stoler, M.D., chairman, was received with thanks. The committee recommended that APA offer help in selecting chairmen of departments of psychiatry where schools have been having difficulties in their search. The Council recommended disapproval of this item and instead recommended that APA ask the American Association of Psychiatric Departmental Chairmen to consider this problem. The Council also noted that a committee of the Group for the Advancement of Psychiatry is working on the issue of unfilled chairmen slots.

The committee recommended consumer representation on the ABPN. The Council approved the recommendation that the Board meet for a day with a group of residents to discuss examination issues.

It also approved the recommendation that directors of residency training programs attend this meeting and agreed that patients used in the exams, while needing protection by the hospital, required no representative on the Board.

The Council disapproved the recommendation that there not be a representative of the public interest on the Board. Instead, the Council recommended that public representatives be invited to sit in on policy sessions of the ABPN and that these representatives have the opportunity to see if the policies of the Board are being carried out, e.g., by sitting in on grading sessions.

The Council endorsed the recommendation which asked that "Lifetime Learning for Psychiatrists" be given wider distribution and be underwritten by APA if funding can be obtained.

The committee discussed the certification of a psychiatrist upon taking a comprehensive examination at the conclusion of

OFFICIAL ACTIONS

Fall Committee Meetings

Following is a summary of the proceedings of the fall committee meetings of the American Psychiatric Association, which were held in Washington, D.C., in October 1972.

The Council on Medical Education and Career Development

ALBERT J. SILVERMAN, M.D., CHAIRMAN

THE MEETING of the Council on Medical Education and Career Development began as requested with extensive discussion of the future of the component parts of the Council. A discussion was also initiated on a proposed reorganization of the Council along more functional lines. This discussion will be continued during the Council's early spring meeting, and the members anticipate presenting a plan for proposed reorganization to the Reference Committee shortly afterward. The Council also made certain recommendations relating to its component parts that will be noted in relationship to its specific reports.

The Council received with thanks a report on the forthcoming Medical Education Conference from Dr. Ewald Busse. The Council recommended that psychopharmacological education be explored during the conference and also recommended liaison with the American College of Neuropsychopharmacology to achieve this end.

The Council received the request that the wording of the APA Membership Certificate be changed to read: "Qualified Psychiatrist.". The Council recommended that since a method of certification in psychiatry already exists and since APA is not a qualifying organization, the proposed change not be approved.

The Council considered the request that a *Task Force on Audiovisual Definitions in Psychiatry* be established. While agreeing in principle that the project had a great deal of merit, the Council recognized that the problems of standardization are considerable and recommended that this proposal be considered in the Council on Research with the Task Force on Nomenclature and Statistics and Committee on Public Information acting as liaisons.

The Council then considered the matter of licensure and certification of specialists as well as that of relicensure and recertification. In view of the fact that an examination route already exists to certify that a person is qualified as a psychiatrist, the Council was opposed to setting up another route. The Council approved the following statement and recommended its adoption as policy by APA:

> Council is in favor of relicensure and recertification of the psychiatrist provided there is full equity and safeguards for the consumer and for the psychiatrist. The consumer would require protection with respect to the competency of the psychiatrist, his need for a psychiatrist, and the status of the patient/doctor relationship.
>
> The psychiatrist would need protection with respect to his right to continue to earn a livelihood. Relicensure and recertification would be meaningless unless there is some method of evaluating credits for continuing education and for the establishment of a national uniform examination that would *reliably* measure clinical competence.

The Council noted that the *Task Force on College Health*, James R. Raybin, M.D., chairman, did not meet. The Council received a position statement previously prepared by this task force and recommended that this position statement be adopted by APA. Since the task force has accomplished its work, the Council recommended that it be disbanded with thanks.

The Council noted that the *Commission on History*, Robert N. Butler, M.D., chairman, had delayed its meeting in order to meet with the Committee on Program later in October.

The report of the *Task Force on Training of Foreign Medical Graduates*, Milton H. Miller, M.D., chairman, was received with thanks. A grant application has been submitted to NIMH for a three-year demonstration program to begin in July 1973. A number of papers have been presented and are being published.

NIMH also proposed sponsorship of a series of programs devoted to the nature, value, and future of North American psychiatric training for Asian psychiatrists. Key Asian psychiatric educators will be guests at the annual meeting in Hawaii in order to participate in these discussions.

Subsequent to the decision of NIMH regarding the grant application, the task force (prior to its expiration in May 1973) will present a series of definitive recommendations regarding APA's role with regard to the foreign medical graduate. The Council approved an extra meeting of the task force, if necessary, to develop these recommendations.

The Council received with thanks the report of the *Committee on Psychiatry and Medical Practice*, Jacob Swartz, M.D., chairman. The colloquium held in San Diego in February

1972 drew 125 participants. The program was considered interesting, but the participants desired more extensive small-group discussions. In August 1972, the committee was invited by the Mental Health Committee of the American Academy of Family Physicians to a meeting in Denver in order to act as consultant for the Academy's NIMH Family Practice training grant and to join in planning for the 11th Colloquium on the Postgraduate Teaching of Psychiatry, which the two committees will cosponsor; the colloquium will be held in Charleston, S.C., in March 1973.

The Council accepted with thanks the report of the newly formed *Task Force on Continuing Education*, James Naiman, M.D., chairman. A recommendation dealing with Dr. Busse's suggestion regarding continuing education, periodic reexaminations, and APA membership was not considered sufficiently clear or precise for the Council's action. If the recommendation could be made clearer, the Council would discuss it at its early spring meeting.

The Council supported the recommendation that groups to instruct teachers be financed by APA in that NIMH refused to finance them; it did not support the recommendation that APA go on record as recommending to departments of psychiatry that they value the teaching of continuing education and that they demonstrate this in relationship to remuneration, promotion, etc.

Regarding the recommendation that APA charge the district branches with generating continuing education plans, the Council expressed the belief that the area council, in collaboration with a nearby medical education center, would be a better vehicle.

The Council also approved in principle the task force's recommendation that the curriculum in continuing education be divided into two parts: 1) basic knowledge required of every psychiatrist, and 2) courses dealing with a psychiatrist's particular area of expertise.

The Council also approved an extra meeting of this task force if necessary.

The report of the *Task Force on Drug Abuse and Drug Education*, Peter Bourne, M.D., chairman, was received with thanks. This task force is preparing an acute treatment manual for drug abuse emergencies in collaboration with the National Clearinghouse for Drug Abuse Information. This would be published and distributed by the National Clearinghouse and was expected to be ready in April 1973; it would include chapters on alcoholism. The Council recommended that this be endorsed as an official joint project between APA and the National Clearinghouse. Two members of the Council would review the completed manuscript, make recommendations to the entire Council, and, through it, to APA for its endorsement.

The Council noted a tentatively proposed moratorium on further federal expenditure in the field of drug abuse education through the mass media. The Council deferred any recommendation on this item until further information has been received.

The Council endorsed the recommendation that training in the field of drug abuse and alcoholism be required by all residency training programs, that some skill in this area be taught to others in the field of mental health, and that APA use its influence to require that the provision of such training be made a requirement in order for training programs to be accredited. The Council further suggested that this information be presented to the self-assessment examiners, to all those involved in continuing education, to the American Board of Psychiatry and Neurology (ABPN), and at the forthcoming conference on medical education.

The task force also responded to a request from the then Secretary of HEW, Elliot Richardson, that APA look at the possible establishment of a training model for leaders in the field of drug abuse. The task force decided to present a recommendation determining whether the guidelines established by the National Institute on Alcohol Abuse and Alcoholism for training in the field of alcoholism can be modified to fit the drug abuse field in general.

In considering the task force's concern about the fragmentation of APA effort in the area of drug abuse, the Council recommended the development of an Ad Hoc Coordinating Committee on Drug Abuse and Alcoholism, consisting of the chairmen of all components that deal with this problem.

The report of the *Task Force on School Consultation*, Sheldon D. Glass, M.D., chairman, was received with thanks. Its appointed task, the preparation of a monograph dealing with this area, was reported to be approximately 50 percent complete. Approval was given for telephone conference calls to facilitate this work; completion is anticipated for fall 1973.

The Council received the report of the *Commission on Manpower*, L. Douglas Lenkoski, M.D., chairman, with thanks. The report recommended that the commission be responsible for data collection, distribution, utilization and manpower operations, and that it exercise an advisory function in relation to the APA Division of Manpower Research and Development. The Council expressed the belief that the work of this commission is most important but recommended that since its operations do not fit into the framework of an educational and training council, the commission be transferred to another council such as Mental Health Services or Research and Development.

The commission also noted that AMA had not approved its request for corrective therapists to be placed on their list of officially approved allied health professionals. The commission has taken no action on the request of art therapists and mental health technologists to be accredited by AMA. The commission reported that in order to do so detailed surveys must be conducted, and staff assistance is essential. The Council decided to discuss this issue at its early spring meeting, in which it will have APA staff input.

The report of the *Committee on Medical Education*, Robert J. Stoller, M.D., chairman, was received with thanks. The committee recommended that APA offer help in selecting chairmen of departments of psychiatry where schools have been having difficulties in their search. The Council recommended disapproval of this item and instead recommended that APA ask the American Association of Psychiatric Departmental Chairmen to consider this problem. The Council also noted that a committee of the Group for the Advancement of Psychiatry is working on the issue of unfilled chairmen slots.

The committee recommended consumer representation on the ABPN. The Council approved the recommendation that the Board meet for a day with a group of residents to discuss examination issues.

It also approved the recommendation that directors of residency training programs attend this meeting and agreed that patients used in the exams, while needing protection by the hospital, required no representative on the Board.

The Council disapproved the recommendation that there not be a representative of the public interest on the Board. Instead, the Council recommended that public representatives be invited to sit in on policy sessions of the ABPN and that these representatives have the opportunity to see if the policies of the Board are being carried out, e.g., by sitting in on grading sessions.

The Council endorsed the recommendation which asked that 'Lifetime Learning for Psychiatrists" be given wider distribution and be underwritten by APA if funding can be obtained.

The committee discussed the certification of a psychiatrist upon taking a comprehensive examination at the conclusion of

his residency and recommended recertification by examination (or possibly by attendance at compulsory courses) at certain intervals. In response to this item the Council called attention to its statement prepared in this regard (cited previously). Also, as noted before, the Council will continue to discuss this issue in reference to the recommendation made by the Task Force on Continuing Education.

The committee recommended that the pamphlet "What Is a Psychiatrist?" be rewritten by staff. APA staff informed the Council that the Board of Trustees would study and further handle this item.

The committee recommended that APA not become a center for the development or distribution of audiovisual materials but instead that the NIMH National Clearinghouse for Mental Health Information be used for collating information about audiovisual material available throughout the country. The Council recommended approval of this item but with a change in wording as follows: "Other organizations such as the National Clearinghouse for Mental Health Information of NIMH be used for collating information about audiovisual material throughout the country."

The report from the *Task Force of Residents*, John M. Scanlan, M.D., chairman, was received with thanks. The Council approved the recommendation that the current task force be dissolved at the conclusion of its work after the annual meeting in Hawaii and recommended that a similar group be appointed at that time. The idea of a group concerned with the involvement of young members of our profession in APA affairs was considered to be an excellent one. However, the issues associated with involvement were not considered to be appropriate for the Council on Medical Education and Career Development. The Council therefore recommended the development of a committee or commission on residents or young members, to be assigned to the Council on Internal Organization or to the Assembly of District Branches.

The Council also received a statement from the task force entitled "Psychiatry Training Funds." This arrived too late to be considered and was held over for the spring meeting.

The Council read the memorandum sent from Dr. Walter Barton, which reminded all councils requesting immediate resident representation of the usual channels through which such requests must go. The Council agreed in principle to the idea of having residents and young members represented at all levels of APA. In this context it recommended that a group of young members work with the Council on Internal Organization or with the Assembly of District Branches.

The Council recommended approval of the request that a resident be selected to attend the meeting of the American Association of Psychiatric Departmental Chairmen in November 1972 and the meeting of Resident Training Program Directors in January 1973. The task force requested permission to have an extra meeting in order to plan a program for the residents' forum at the APA annual meeting, to draft a final report of the task force's activities, to plan a national residents conference, to clarify the relationship between the task force and the Falk Fellows, and to develop a clear statement about the goals and objectives of the recommended new Task Force on Residents. The Council approved these requests.

The report of the *Committee on Academic Education*, John F. McDermott, M.D., chairman, was received with thanks. This committee saw its next phase as one of involvement with current issues in general education. This included looking at non-medical education and at problems related to child development, the underlying theme being primary preventive psychiatry and the development of a number of task forces on school busing, education of teachers in child development, racism, special education programs, etc. The Council recommended continuing this committee along the lines suggested here.

The report of the *Task Force on Family Life Education*, Arnold M. Kallen, M.D., chairman, was received with thanks. A manual on this topic was being prepared and should be finished in the allotted time. Cooperative ventures concerning this topic were being developed between APA and other groups.

The task force requested APA endorsement in order to enable it to plan official APA meetings to which representatives of other organizations would be invited. If this is endorsed, the task force would seek funds separate from the APA budget for these activities. The Council recommended approval and also recommended another year of life for this task force, if necessary, to get the activities noted here under way.

The report of the *Committee on Certification in Administrative Psychiatry*, Archie R. Foley, M.D., chairman, was received with thanks. The Council approved the revised edition of the rules and regulations and of the application forms that had been previously received. The Council also noted the editorial changes and approved their inclusion.

The Council did not approve that portion of the report which indicated that "the Committee will assume responsibility for dissemination of the information in the new guidelines to those segments of the profession which their members represent and for working for greater reliance on the certification procedure as a meaningful criterion for including administrative competence." The Council expressed the belief that the approval of all activities of this committee should come from official APA channels; this would include dissemination of guidelines. The Council further had serious questions about any APA committee having the responsibility for certification. (About two years ago the Council referred this matter to the ABPN, which sent it back stating they already had too much to do without taking this task on.) The Council recommended that this matter again be referred to the Board as falling within its responsibility. The Council decided to discuss this item further at its spring meeting.

The Council questioned the advisability of holding an examination during the Hawaii annual meeting since it had been informed that only a limited number of applicants would like to take it then. However, it was decided that if agreements had already been reached with APA leaders regarding such an examination, the Council would not recommend disapproval.

The task force report referred to a document summarizing the deliberations of the Task Force on Continuing Education in Administration for Psychiatrists, which was sponsored by the APA Office of Continuing Education and funded by the Continuing Education Branch of NIMH. The Council had not received this document and could not respond.

The committee also stated that it would function with greater continuity and cohesiveness if its members had longer appointments such as would be obtained by becoming a commission. The Council recommended that if the certifying function now carried out by this committee remained within APA and was not transferred to the ABPN, as recommended, then serious thought should be given to changing the committee to a commission.

The Council on Mental Health Services

EDWARD O. HARPER, M.D., CHAIRMAN

DURING THE PAST YEAR, the Council on Mental Health Services, together with its task forces and committees, has worked diligently to prepare position statements and make recommendations that, it is hoped, will improve the delivery of mental health services to all U.S. citizens.

The *Task Force on Aging*, Alan I. Goldfarb, M.D., chairman, submitted a position statement on aging that embraced many of the recommendations made by the 1971 White House Conference on Aging. The report emphasized the following six major points:

1. APA believes that there must be comprehensive and effective delivery of mental health services for all citizens. There is urgent need for improvement in the mental and physical health care of elderly citizens. A comprehensive system of health care should be established that provides for: a) proper evaluation of the individual's health needs; b) psychiatric, medical, social, and supportive measures, not only to maintain health, but also to rehabilitate the sick and infirm; c) continuity of long-term care; and d) preventive health measures together with an ongoing educational program encouraging the preservation of health in all ages.

2. The health services provided by hospitals and health and welfare agencies should be carefully correlated and integrated with other agencies providing for the well-being of the aged. Because of their multiple disabilities, geriatric patients should have the same quality of inpatient and outpatient care in general hospitals as do all other patients. Inpatient and outpatient facilities of state psychiatric hospitals should be upgraded and expanded to provide for those elderly patients whose mental and physical infirmities necessitate long-term hospital care. Expanded and improved social services should also be available.

3. Elderly patients with no clearly defined psychiatric illness may have their needs for protective care best served in comfortable, friendly, home-like congregate living accommodations that have adequate psychiatric supervision and staff.

4. Substantial increases in financial support for all medical and psychiatric services are immediately necessary. Funds should be made available from federal, state, county, and city governments and from third-party payment, together with such fees from patients as do not impose a financial burden. Medicare benefits should definitely be increased in the following manner: a) there should be elimination of all deductibles; b) psychiatric services should be paid for on the same basis as all other medical and surgical services; c) there should be no exclusion of psychiatric patients from nursing home care when this is most helpful; and d) funds should be divided among services, research, and education.

5. The curricula of medical schools should provide for the teaching of geriatrics including not only psychiatric, but also medical and surgical, illnesses. Instruction concerning the needs of elderly citizens should be included in the educational programs of nurses, medical aides, and paramedical personnel.

6. APA strongly advocates the establishment of a Center on Aging in the National Institute of Mental Health and a National Institute of Aging, with special emphasis on the study of biomedical problems. APA also urges its President to appoint an interdisciplinary commission on aging for the overall monitoring of government agencies and pledges its active participation in the deliberation of such a body.

The *Task Force on Peer Review*, Rives Chalmers, M.D., chairman, submitted a far-reaching report recommending guidelines for peer review (see March 1973 issue of the *Journal* for position statement). This was approved by the Board of Trustees and the Assembly of District Branches.

The report of the task force recognized the great public insistence that there be quality and cost control in all phases of health care delivery. The philosophy underlying peer review is based on the principle of quality health care for all. The report stressed the need for positive, effective action on the part of organized psychiatry in promoting the development of a peer review organization at both the district branch and the national levels. A cardinal goal of peer review is to improve the quality of care through the continuing education of physicians, other providers, and patients in the method for providing and receiving better care at minimum feasible cost. Accordingly, the task force recommended that APA establish a program for peer review that would function within each district branch, together with a standing APA committee.

Each district branch peer review organization should take an active part in consulting with the local medical peer review organization and with third-party carriers. This peer review organization should be made up of three knowledgeable members of the district branch who have varied experiences. It should function as a specialty consultant peer review organization and as a broader medical society peer review mechanism. It would serve as a regional extension of APA.

Continuing feedback to district branch membership of peer review experiences, decisions, and accompanying changes in practice is the basic element in developing an effective peer review organization. A well-defined and broadly publicized input mechanism should be available to physicians, care recipients, and interested third parties on questions concerning patient-generated services.

There should be a clearly established appeals chain for disagreements over decisions, preservation of confidentiality, immunity from litigation, and protection from discovery. The decisions and records of the organization's proceedings should have adequate safeguards to prevent their use against the physician whose services are being reviewed. Eventually, review procedures should be standardized with the hope that a multiple-specialty medical society will increase the objectivity of the entire peer review mechanism.

The development of the local peer review organization and the success of a constructive mechanism will depend on the successful integration of three major programs: 1) an automated system for the collection, identification, dissemination, and storage of data, with an available retrievable system; 2) a research structure to provide exploration into problem areas as they are delineated; and 3) an educational program designed to effectively return accumulated information to the physician, recipients of care, and third-party carriers. According to the task force report major objectives would be: 1) the education of physicians: peer review would be an effective means for promoting communications concerning quality of care and unusual concepts of fees prevailing in a given medical community; 2) the evaluation of quality: within this area continuing feedback through an accepted educational program will further the effectiveness of any information gathered; 3) evaluation of costs; and

4) evaluation of quality/utilization.

Data concerning the use of a psychiatrist's time—the hours devoted to patient care, administration, teaching, and supervision—could be obtained. This in turn may make possible new therapeutic approaches that would reduce the time required of the psychiatrist and paramedical personnel and the cost to the patient without compromising the quality of the care.

The Council has requested this task force to carry on its work through the period of implementation.

The *Task Force on Psychiatric Rehabilitation in Correctional Systems* is the new name of the group formerly called the Task Force on Prison Reform. This name reflects more clearly the charge that the task force had been given. The new chairman is Francis A. Tyce, M.D.; he replaced Harold Janney, M.D., who asked to be relieved of his responsibilities because of illness. The Council expressed its regrets that it was necessary for Dr. Janney to relinquish his membership.

The Council did not recommend APA endorsement of the proposed White House Conference on Correction; it appeared that this conference would focus primarily on detention and penology rather than on the problems centering around rehabilitation.

The *Task Force on Private Psychiatric Hospitals*, John H. Houck, M.D., chairman, was composed of the same members who submitted the report on the status of state psychiatric hospitals. In that report emphasis was placed on the importance of the state psychiatric hospital in the mental health of the community despite the counter claims of those who would downgrade its function. The task force was collecting data on the bed capacity and the cost per day of the private psychiatric hospital as compared with the state hospital. The quality and the type of care delivered in these hospitals was being studied and will be compared with the cost and quality of care delivered in public hospitals.

The *Committee on Financing of Mental Health Care*, John M. Cotton, M.D., chairman, met with key individuals in Medicare, Medicaid, CHAMPUS, and others. The committee has continued to be actively involved in various local and national efforts relating to health insurance and the perplexing problem of the cost of psychiatric care.

The American Hospital Association has studied the cost of medical services in depth. Dr. James Johnson participated in these discussions. When the results of the study are available, APA will participate in a national conference on the cost of medical services. The committee proposed a statement on the National Association for Mental Health's position statement "Categories of Service for Mental Health Coverage Under National Health Insurance."

The *Task Force on Suicide Prevention*, Matthew Ross, M.D., chairman, was trying through every possible channel to gather hard data on the incidence of suicide among psychiatrists. It is extremely difficult to obtain accurate data about this group. The task force expressed the belief that special emphasis should be placed on psychiatrists since too little attention has been paid to those colleagues who are in desperate need of psychiatric help.

The Committee on Federal Government Health Services, Van Buren O. Hammett, M.D., chairman, has been studying many facets of the health services in the Armed Forces. It has been immediately concerned with the problem of drug abuse in the Armed Forces. The committee was also looking into the status of psychiatric services in the Veterans Administration.

The Council has been concerned about standards for community mental health centers. A task force was not appointed to study this problem since a Task Force on Evaluation Research in Community Mental Health Centers already exists under the Council on Research and Development. An ad hoc committee will study the Nader report on community mental health centers. The Accreditation Council on Psychiatric Facilities has been studying this problem, and the Task Force on APA Standards for Psychiatric Facilities, which the Council has established, will make necessary recommendations concerning standards for community mental health centers.

The Council recommended to the Ad Hoc Committee on Current Procedural Terminology that the AMA document should include a provision for psychiatric consultation with a private and/or public health welfare agency and that a preparatory statement be made concerning the use of procedural terminology and especially the coding of time.

The Council established a *Task Force to Study the Status of Nursing Homes and Other Extended Care Facilities*, Arthur L. Arnold, M.D., chairman. The charge given to this task force is to evaluate the quality of care and the standards to be met by these facilities and to make necessary recommendations for improving the care given to patients in these facilities.

The quality of care following discharge from state psychiatric hospitals is at times unbelievably poor. The care and support that many of these patients receive after hospitalization is grossly inadequate. This issue, however, will be considered by the Council at the next meeting.

The Council also established a *Task Force on APA Standards for Psychiatric Facilities*, William S. Allerton, M.D., chairman. The charge of this task force is to review and revise the APA standards where necessary, giving careful attention to the recent Alabama court decision concerning psychiatric hospitals. This decision has made it necessary for APA to again carefully review the standards for psychiatric facilities.

The Council established a *Task Force on Collaboration of the Psychiatrist and Consumer in Psychiatric Programs.* The charge of the task force is to consider the mutual roles of the psychiatrist and the consumer in the delivery of mental health services, to study and evaluate existing models of participation, and to make recommendations for future collaboration. The chairman and members of this task force have not yet been appointed.

Staff is working with the draft of the report from the *Task Force on Private Enterprise Models.* The name of the document has been changed, and it was announced that the new draft will be available soon. The Assembly of District Branches now has a Task Force on Private Practice.

The Reference Committee recommended to the Board of Trustees that the current Commission on Manpower be allowed to terminate in May 1973 and that an advisory group to the Division on Manpower Research and Development be formed and assigned to the Council on Mental Health Services for administration and funding.

The Council referred for study to the Task Force on Peer Review and to the Task Force on Psychiatric Rehabilitation in Correctional Systems the possibility of an increase of psychosurgical procedures and the reactions to them.

The Council was delighted to have the following Falk Fellows participate in its activities, its committees, and its task forces: Drs. Travis W. Jenkins, John Looney, Richard Dorsey, and Arthur B. Schuler. They brought to its deliberations a special expertise that was very much needed.

The Council on Research and Development

RUSSELL R. MONROE, M.D., ACTING CHAIRMAN

DURING THE FALL OF 1972, Sidney Malitz, M.D., was recovering from two illnesses so the vice-chairman of the Council on Research and Development assumed the role of acting chairman. It was reported that Dr. Malitz would resume his activities as chairman of the Council at the Reference Committee meeting, February 8–9, 1973.

Two task force reports were approved by the Council with the recommendation that these be published as task force monographs. These recommendations were submitted to the Reference Committee.

The first report, entitled "Behavior Therapy in Psychiatry," was completed by the *Task Force on Behavioral Therapy*, Carl Lee Birk, M.D., chairman. This task force was established to study the historical development of behavior therapy, its efficacy for the treatment of psychiatric problems, its current forms and uses as well as potential abuses, and its relationship to dynamic psychiatry. The Council felt that this would be an invaluable introductory monograph for psychiatrists, psychiatric educators, psychiatric residents, and medical students. It is hoped that the report will provide an impetus for mutually beneficial interactions between dynamic psychiatrists and behavioral therapists.

The second report, also recommended for publication as a monograph, was that of the *Task Force on Vitamin Therapy in Psychiatry*, Morris A. Lipton, M.D., chairman. This was a scholarly review of the 20-year history of Vitamin B^3 therapy (nicotinic acid or nicotinamide) for the treatment of schizophrenia. The report also included an up-to-date summary of attempts to replicate the claims of proponents of this treatment method. It is hoped that with the publication of this report an APA position statement on megavitamin therapy can be issued.

In collaboration with the *Commission on Drug Abuse*, Daniel X. Freedman, M.D., chairman, a position statement on the value of amphetamines in the pharmacologic armamentarium of the psychiatrist will be presented to the Reference Committee, the Board of Trustees, and the Assembly of District Branches for their consideration.

On recommendation of the Council, the Reference Committee approved the discontinuation of the *Task Force on Systems Theory in Community Mental Health* and of the *Task Force on Current Problems in Research Support.* However, the Reference Committee suggested that the Council might consider a task force that would develop general guidelines for research support.

Membership was approved for the revived *Task Force on Lithium*, Irvin M. Cohen, M.D., chairman. This task force will investigate the status of lithium therapy in other than the manic phase of manic-depressive psychosis.

Four new task forces were recommended by the Council and approved by the Reference Committee. These include: 1) a Task Force on Psychiatric Aspects of Aerospace Program, 2) a Task Force on Biofeedback, 3) a Task Force on Meditation, and 4) a Task Force on Research Aspects of Psychosurgery.

The *Task Force on Research Aspects of Psychosurgery* will work in liaison with a similar task force under the Council on Emerging Issues evaluating the social impact of psychosurgery. The task force under the Council on Research and Development will focus on a critical evaluation of follow-up studies and on the scientific merits of current research in psychosurgery.

The *Task Force on Evaluation Research in Community Mental Health Centers*, Gerald L. Klerman, M.D., chairman, completed a report in 1971; 2,000 copies were printed and distributed to mental health centers throughout the United States. This task force was continued at the request of government agencies and now functions as a consultant to them. The task force has been in consultation with NIMH and HEW regarding a program for evaluation research. It is now preparing for consideration by the Council a brief paper defining the issues, including the priorities, scope, and administrative mechanisms of evaluation research.

The *Task Force on Methadone Therapy and Narcotic Antagonists*, Roger E. Meyer, M.D., chairman, was active in developing a survey questionnaire utilized by the Food and Drug Administration (FDA) and the Special Action Office of Drug Abuse Prevention for surveying methadone maintenance treatment centers throughout the United States. The task force presented to the Council preliminary data collected during this survey. It also reported that it had submitted 19 recommendations to FDA regarding the evaluation of effective methadone programs. A report will be submitted to the Council before its next meeting regarding current guidelines for methadone therapy, along with a report on the status of narcotic antagonists as a therapeutic regimen for the treatment of addicts.

The *Task Force on Nomenclature and Statistics*, Henry Brill, M.D., chairman, reported that it was cooperating at the international level in preparing a glossary to be included with the new ninth edition of the *International Classification of Diseases (ICD-9)*, which is now in preparation and is expected to be published in 1976. Dr. Brill spent from August 28–September 4 in Geneva with Jack Ewalt, M.D., working on an advanced draft of this glossary. Dr. Brill reported that a major change in *ICD-9* will be the adoption of dual coding of organic states, utilizing one number for the clinical syndrome and another number for etiology. He also anticipated major changes in the child psychiatry section. Otherwise, he felt that the final version will not vary extensively from *ICD-8*.

The *Task Force on Clinical Aspects of the Violent Individual*, Donald P. Kenefick, M.D., and John R. Lion, M.D., co-chairmen, anticipated that it would have a report available for consideration by the Council at its spring meeting. It hoped that the report would be published as a guideline for the identification of and treatment planning for the violent individual.

Two new task forces have had their first meeting in liaison with the Council and are now developing specific changes. These are the *Task Force on Ethical Problems in Psychiatric Research*, Sidney Merlis, M.D., chairman, and the *Task Force on the Effects of Television on Mental Health*, James H. Ryan, M.D., chairman.

The *Task Force Relating to Research Evaluation of Racism* has not been activated. However, under the impetus of Walter W. Shervington, M.D., who is observer-consultant to the Council, it was hoped that this task force would be constituted by the next meeting of the Council.

A position statement formulated by the disbanded Task Force on the Confidentiality of Medical Research Records was submitted to the Reference Committee for approval of publication. This report was approved by the Reference Committee in

1970 but has not been published. The request of the task force was approved by the Reference Committee and by the Board of Trustees and will be submitted to the Assembly of District Branches for its approval.

Dr. Albert B. Silverman, chairman of the Council on Medical Education and Career Development, pointed out that the Commission on Manpower was to be disbanded in 1972. He suggested that inasmuch as the Division of Manpower Research and Development was part of the staff function of APA, a new committee to advise this office should be appointed and that such a committee might be assigned to the Council on Research and Development. Dr. Monroe suggested that such a committee would be appropriate under the aegis of the Council on Mental Health Services, although specific activities that call for a task force might be assigned to the Council on Research and Development. This recommendation was accepted by the Reference Committee.

Dr. Monroe raised the issue of task forces' representing themselves to outside agencies, either government or private, as official spokesmen for APA. It was recommended and generally approved by the Council chairman and the Reference Committee that specific detailed guidelines for the activities of task forces should be given to their chairmen and should particularly emphasize that statements made to outside agencies be cleared with the Council, Reference Committee, and Assembly of District Branches. It was suggested that in an emergency, telephone conferences regarding important matters could be arranged.

The Council expressed its appreciation for the valuable participation of the Falk Fellows during the fall meeting. These were Stuart C. Yudofsky, M.D., and Fritz Henn, M.D.

The Council on National Affairs

LAWRENCE C. KOLB, M.D., CHAIRMAN

THE COUNCIL ON NATIONAL AFFAIRS was in the process of reorganization in that three new members, Drs. J.I. Barish, D.S. Sanders, and its chairman, have been newly appointed. It is fortunate that its previous chairman and vice-chairman, Drs. Alexander H. Leighton and James M. Bell, continue. The Council pursued its work through telephone conferences held in July and November 1972 and in January 1973. The Council received and reviewed reports from the various committees and task forces assigned or appointed under its jurisdiction.

The Council heard and received a full report of the actions of the *Task Force on Aggression and Violence*, John P. Spiegel, M.D., chairman, from its inception in May 1968. Over the four years the task force reviewed the reports of the Eisenhower Commission; framed a number of hypotheses and questions for research pertaining to violent behavior; played a major role in developing the program of the annual meeting in Washington, D.C., on violence and alternatives to violence; reviewed various books on these subjects for *Psychiatric News*; conducted a questionnaire survey of the membership at the 1971 annual meeting to determine those who were interested in work in aggression and violence; developed, arranged, and participated in an essay contest relating to violence; reviewed a gun control resolution; and reviewed a resolution prepared by the Task Force on Violence and Alternatives to Violence of the Assembly of District Branches.

Following discussion of the work of the task force, the problems it had faced in its efforts, and possible future action, the Council unanimously passed the following recommendation:

> For their outstanding efforts on behalf of the Association during a most difficult and troublesome time in its history and in that of our country, the Council commends their outstanding and important efforts. In recommending now the discharge of the task force, the Council requests that the President of the Association express in writing to each member of the task force, and particularly to its chairman, the gratitude of the officers and members of the Association for their efforts.

Prior to taking this action, the Council recommended that the task force present a proposal for continuing work in the important new area they have recently been examining—third-party intervention in community affairs. The council received that proposal and recommended the following to the Reference Committee:

> The APA Council on National Affairs recommends the establishment of a Task Force on Third-Party Intervention in Community Crises for the purpose of exploring, over a period of one year, the feasibility of involving members of the Association in this effort. It is hoped that the task force will contact organizations nationally recognized for their work in this area and offer assistance and collaboration on behalf of APA, while at the same time contacting potentially interested APA members in local communities threatened with violence. It is further recommended that at the end of the exploratory year the task force submit a report to the Council on National Affairs in regard to the prospects for further fruitful work in this area.

Both the Reference Committee and the Board of Trustees approved these recommendations.

The *Task Force on Indian Affairs*, Morton Beiser, M.D., chairman, developed a contract request with the Indian Health Service entitled "A Survey of Service Network and Utilization Patterns of Mental Health Programs in the Indian Health Service." The contract was approved with a budget of $24,939. Another contract, with a similar function and with funding of $5,000. was negotiated with the State of Maine, and the contract funding has been paid to APA. Members of the task force examined the utilization of community mental health centers in California, the Pacific Northwest, and Montana and developed training programs for Indian mental health personnel. They also engaged in discussions with Canadian colleagues regarding Indian mental health services in British Columbia. The task force had a special meeting with Dr. Emory Johnson, Director of Indian Health Services, on October 13, 1972.

The *Task Force on Environment and Mental Health*, Aristide H. Esser, M.D., chairman, was urged to define its objectives more specifically. The members contemplated meeting in February 1973 to complete their work. They presented a position statement regarding their past work in writing papers on environment and mental health, preparing a bibliography in this area, and participating in a workshop at the 1972 annual meeting. The task force proposed its own dissolution in May 1973, with establishment of new task forces on: 1) ecopsychiatric data base, 2) criteria and methodology for assessing the quality of life, and 3) environmental impact statements. The Council referred to this task force a letter from the Medical Director written to obtain its opinion about whether the proposed new task forces on the effects of unplanned population growth and family planning fall within their purview.

The *Task Force on Delivery of Psychiatric Services in Poverty Areas* made three recommendations: 1) that its leadership through the cochairmen, Orlando B. Lightfoot, M.D., and Quentin Rae-Grant, M.D., be continued; 2) that APA continue to exert maximum influence to avoid a decrease in funding for community mental health centers, particularly in poverty areas; and 3) that it be granted permission to meet and to prepare its report. The Council approved the recommendations, as did the Reference Committee and the Board of Trustees.

The *Committee of Black Psychiatrists*, J. Alfred Cannon, M.D., chairman, met with mental health professionals from a number of NIMH divisions and sections. In this meeting the following topics were discussed: the relationship of the APA Office of Minority Affairs and the Minority Center of NIMH; the Administration's decision to reduce the quota system with regard to the hiring of members of minority groups; the effect of reduction in the training funds for psychiatrists in general and, specifically, the effects on the training of black psychiatrists; and the issue of prison reform. The committee agreed that special efforts be made to institute reform in the correctional institutions for preadolescents and adolescents. The committee urged that APA speak out on the origins of criminal behavior in broken families and on judicial and penal reform. Regarding judicial and penal reform it was believed that the emphasis should shift from intervention after imprisonment to intervention, prevention, and rehabilitation, as well as the use and misuse of psychiatric diagnosis, in parole and sentencing.

The committee concerned itself with the psychological implications of black "exploitation films." Recent statistics, which seemed to show an increased number of blacks with serious psychiatric illnesses, stimulated the committee to recommend that APA urge organization of more community-based treatment facilities and curriculum changes in psychiatric training whereby all practitioners would become acquainted with the particular cultural nuances of blacks and other minorities and their application as far as diagnosis is concerned. The committee noted the structure of various research programs concerned with minority populations and propounded a philosophy of approach in order to further studies of this kind in the future.

The Council reviewed the committee's report and is seeking operational recommendations.

The *Task Force on Mental Health of Spanish-Speaking People in the United States*, Angel G. Gomez, M.D., chairman, will continue efforts to develop information in the area of its concern. Statistics show there are currently 16 million Spanish-Americans within the continental United States and 28 million in Puerto Rico. The United States has the fifth largest Spanish-speaking population in the world. In 1970–1971 no one in psychiatric residency training was a Mexican-American. The task force suggested to the Council a series of mechanisms to deal with various actions concerned with the well-being of the Spanish-speaking population. The Council noted these at its last meeting and advised the task force to take steps to prepare contract or grant proposals to assist in efforts to collect necessary data.

The *Task Force on Comprehensive Health Planning*, Robert L. Williams, M.D., chairman, recommended that "the administration of APA become actively involved in making recommendation for changes in the law relating to comprehensive health planning and the regulations related thereto." The Council approved this recommendation, as did the Reference Committee and the Board of Trustees.

Specifically, the task force has leaned toward the opinion that APA should take a stand on merging mental health planning with comprehensive health planning and eliminating the separate funding category for mental health. The Council has not debated this point of view. It noted, however, the evidence obtained from the task force's work of a lack of involvement and information at the state levels of APA.

The Council recommended, in response to the request of APA President Perry C. Talkington, M.D., that all district branches be requested to discuss involvement in comprehensive health planning actions within their states and the merits and demerits of fusing the planning and funding of mental health with comprehensive health planning.

The Council on Emerging Issues

EDWARD T. AUER, M.D., CHAIRMAN

THE COUNCIL SPENT CONSIDERABLE TIME discussing some of the operational concepts members had about it. Strong sentiment was expressed that the Council should limit its deliberations and considerations to areas in which it felt it could speak from the role of the psychiatrist as a professional person. Some interest was expressed in the attempt to define this role.

It was indicated that the Falk Fellows and residents have an active concern about role definition. The thought was expressed that some steps have been taken toward the clarification of the confusion involved when psychiatric units attempt both to provide professional services to patients and to perform a public health service at the same time. A possible emerging issue was identified as the need for some clarification of the professional role or roles of the psychiatrist in the 1970s.

The concept of the Council operating as a "dew line" for emerging issues for APA was discussed. Most members accepted this concept as one they would like to work with. The need to establish effective communication with "sensing points" (e.g., the Central Office, district branches, etc.) was discussed, as was the need to respond to matters brought to the Council's

attention by conference calls, interim meetings, etc.

The *Task Force on Women*, Nancy A. Roeske, M.D., chairwoman, was appointed recently. Dr. Perry Ottenberg will act as liaison representative from the Council. The task force held its first meeting on November 11, 1972, in Philadelphia. In preparation for this meeting it developed a bibliography of current relevant articles and had obtained and was reviewing a survey conducted by the Task Force on Women of the American Psychological Association. The task force requested time for a panel discussion to be held at the 1973 annual meeting.

The Council discussed at some length the question of how it should respond to the problems of increased use of psychosurgical techniques. The members had all reviewed the statements by Dr. Peter Breggin, which were read into the *Congressional Record* this year. The Council felt that there are currently five areas relative to this issue that required attention:

1. The need for a more objective review of the literature than is currently available. Dr. Auer and Dr. Malitz were to explore the mechanism for accomplishing this.

2. The Council was told by Dr. Barton that the Mississippi District Branch had developed guidelines for evaluating patients considered for lobotomy. These guidelines will be obtained and reviewed and then circulated to other district branches for their information, along with a request that they react to them. Based on these responses, the Council will prepare a report for the Executive Committee of the Board of Trustees. It was hoped that this could be reported to the membership at the 1973 annual meeting.

3. The Council was cognizant of the political aspects of the problem of lobotomy and believed that they could be considered in conjunction with Dr. Waggoner's Ad Hoc Committee on the Use of Psychiatric Institutions for the Commitment of Political Prisoners.

4. The Council saw some relevance of this problem to the general question of organized opposition to scientific change and wondered if any task force or committee was currently addressing itself to this general problem.

5. The Council expressed the belief that APA task forces and committees concerned with peer review, quality of care, and prisons or corrections should be reminded of the possibility of increased use of psychosurgical procedures; their reactions to these procedures might require some special attention.

The Council reviewed correspondence from Dr. Robert Cancro and Dr. Eugene Brody, both of whom are interested in the general area of family planning. Dr. Auer had a long discussion with Dr. Cancro about his interest and then sent a fairly detailed letter to the Council that, in essence, requests the appointment of a task force to do a feasibility study of the possibility of developing conceptual and mathematical models that would simulate the results of unplanned population growth. Dr. Brody met with the Council and indicated his interest in the appointment of a task force to plan and seek outside funding for a conference that would deal with the various psychosocial and psychocultural barriers to family planning. He envisioned this as an interdisciplinary conference and hoped it would help clarify the need for psychiatric involvement in family planning.

The Council unanimously supported the appointment of a Task Force on Psychiatric Involvement in Family Planning. It was hoped that Dr. Brody would accept the chairmanship and that Dr. Cancro would accept membership. The charge of this task force would be to plan and to conduct a conference on the psychosocial and psychocultural aspects of family planning. It was understood that such a conference would require funding from sources other than APA.

The Council reviewed correspondence to Dr. Barton from Walter J. McNerney, president of the Blue Cross Association, requesting that the APA endorse the Blue Cross position regarding no-fault automobile insurance. The Council recommended that this position taken by Blue Cross be forwarded to district branches for their information and appropriate action at the state level. It was suggested that this might be an issue that could be used for improving the relationships between the Blue Cross and APA district branches. It was hoped that the district branches would communicate with the Council over issues that evolved as a result of such action.

The Council discussed the request that APA take an official position and action regarding gun control legislation. Dr. Talkington and Dr. Ameen informed the Council that the Assembly of District Branches had passed a resolution on gun control (see March 1973 issue of the *Journal*). The Council was not aware of the current status of that resolution. Since the Council understood that the resolution suggests a position, it believed that its current status should be reviewed by either the Reference Committee or Executive Committee at their next meeting.

The Council reviewed correspondence from Dr. Alfred Fireman requesting the establishment of a Task Force to Study the Psychiatric Consequences of Increased Free Time in the American Society. The Council declined to take action on this proposal and generally questioned whether leisure time was not more appropriately the concern of other professions. It was noted that the only persons Dr. Fireman suggested as task force members were from the disciplines of sociology and corrective therapy. Some consideration was given to the possibility of a study of the way in which psychiatrists spend their leisure time and even to the possibility of correlating such data with the multiphasic screening of members on a voluntary basis at an annual meeting. This consideration was tabled.

The question of APA participating in active planning for the return of prisoners of war (POWs) was discussed. The Council took the following action: 1) Dr. Auer was to make contact with the Department of Defense research team involved in this and find out what, if any, association they desire; and 2) Dr. Ameen was to bring this question to the attention of the Assembly of District Branches at its meeting in November.

The importance of having counseling available to families of returning POWs was discussed. The anticipation of problems generated by the POW's dreams about his family and home, their dreams about him, the pressures by the media and other social and cultural factors that make it difficult for real feelings to be expressed (e.g., the taboos against mental disruption even when it was already in process before the man became a POW)—all should be considered by those who might be involved in providing assistance or consultation to these men and their families. Questions evolved regarding the special problems of the Viet Nam veteran. Copies of a recent report on this topic were to be reviewed by the Council.

Dr. Stanley Dean visited briefly with the Council, requesting the establishment of a Task Force on Psychiatry and Psychic Phenomena. The Council did not wish to support the appointment of such a task force.

The Council reviewed the recommendations of the *Task Force of Residents* that residents be appointed to all task forces, committees, commissions, and boards, as well as councils. The Council endorsed the concept of residents who are members of APA being appointed as recommended. Two residents are currently assigned to the Council, and one resident was invited to join the Task Force on Women. The Council informed the Task Force of Residents about these assignments.

In the future the Council hoped to consider the delineation of the psychiatrist's role, the impact of the mass media on behavior, and random and street violence.

The Council on International Affairs

HOWARD P. ROME, CHAIRMAN

DR. NORMAN ROSENZWEIG presented the report of the Council on International Affairs for Dr. Rome, who was unable to be present.

The continuing activities of the *Inter-American Council of Psychiatric Associations*, a group representative of psychiatry in the Americas, was reviewed by the Council. The plans for a Second Inter-American Congress on the Mental Health of Children and Youth, which was to be held in Puerto Rico, September 28–October 3, 1972, were highlighted.

The format of the congress was reviewed in detail, including the innovation of its two-part program: 1) the Working Conference—concerned with the collation of the mutual committees' reports on four topical areas, and 2) the Institute—composed of invited participants who would not have previously participated in the preparation of data but who would have had the opportunity under the aegis of the Preparatory Commission to discuss the items developed at the plenary session of the institute.

The next meeting of the Inter-American Council was planned for Mexico City, January 4–5, 1973. The scientific session, which is a regular part of the meeting, was to have as its theme "Inter-American Cooperative Studies of Drug Abuse Prevention," arranged by Dr. Guido Belsasso.

It was anticipated that the new constitution would have been ratified by all of the signatory associations and would provide a smoother organizational procedure.

A proposal to the Council by Dr. Norman Rosenzweig had to do with the establishment of an International Liaison Task Force. Its purpose would be to create a more formal network of members in APA to facilitate an interchange of mental health information.

Dr. Rosenzweig was delegated to contact the district branches to learn who from their membership might be interested in this communications activity.

Jorge Velasco-Alzaga described at length his plan for the establishment of the Instituto Mexicano de Hygiene Mental. He offered its housing facilities on a permanent basis to the Secretariat of the Inter-American Council of Psychiatric Associations.

Among other activities, the Instituto was planning to be an international exchange center for teaching, research, and limited outpatient services. Its physical plant was anticipated to cost $1 million. It would provide a locus for university fellows, World Health Organization personnel interested in epidemiological studies, public health nursing, etc.

Summary reports on the status of the Council's *Task Force in Liaison with the Canadian Psychiatric Association* and *Task Force on Crisis Intervention* were presented.

The *Task Force on the Joint Meeting in Australia, 1975*, Alfred Auerback, M.D., chairman, did not meet during the October meetings but reported that its plans were proceeding well.

The Mexican Center for the Study of Drug Abuse has been established for transcultural research and exchange of information in the area of drug abuse. Two meetings have been held between U.S. and Mexican representatives, with Dr. Rome participating.

The *Task Force on Transcultural Psychiatry*, Ramon Parres, M.D., chairman, and the *Task Force on Psychiatry and Foreign Affairs*, William D. Davidson, M.D., chairman, reported that they continue to plan and participate in scientific symposia, panels, and the 1973 APA annual meeting. The Task Force on Transcultural Psychiatry invited Falk Fellows to attend the World Congress of Psychiatry with local funding and participated in a joint U.S.-Mexican drug abuse exchange. The Task Force on Psychiatry and Foreign Affairs was planning a seminar on federal policy-making processes at the Brookings Institution in Washington, D.C., and a special session on the India-Pakistan question for the 1973 annual meeting, and contributed to the Pugwash Science Conference.

The Council on Professions and Associations

ROBERT S. GARBER, M.D., CHAIRMAN

APA's PRESIDENT, Dr. Perry Talkington, asked the Council on Professions and Associations to introduce a discussion of topics with high priority that could be assigned to the district branches for the development of position statements. The 12 topics follow:

- Expansion of continuing education for psychiatrists. It was pointed out that there needs to be an expansion by way of conducting examinations on the content of *The American Journal of Psychiatry, Psychiatric News*, and *Hospital & Community Psychiatry*. There also needs to be an expansion in the teaching sessions at APA annual meetings.
- Focus on ambulatory care, particularly the emergency room crisis.
- Including within the emerging health maintenance organization (HMO) concept the provision of psychiatric services.
- Stimulating attendance at local scientific meetings.
- The deteriorating quality of urban life.
- The continuing problem of interprofessional relationships, which should include a redefinition of the functions of the psychiatrist.
- The role of the psychiatrist vis-à-vis the newly emerging mental health workers.
- Definition of the psychiatric team. Is it a myth?
- The psychiatrist in private practice as a model for training.
- The current denigration of hospital care.

- The increased tolerance of deviant professional behavior.
- The social attitude toward psychiatric illness.

The *Task Force on Interprofessional Relations*, William W. Zeller, M.D., chairman, submitted a position statement on "The Psychiatrist: Relationships with Nonmedical Mental Health Professions." The revised and edited document was turned over to Dr. Hammersley for duplication so it could be submitted to the Reference Committee for its approval. The statement contained input from the Assembly of District Branches, as well as from APA's legal counsel, Mr. Warren McGee, in regard to the legality of certain statements. The Council unanimously concurred in the recommendation that this statement be approved by the Reference Committee. (See March 1973 issue of the *Journal* for the position statement.)

The *Task Force on Confidentiality as It Relates to Third Parties*, Maurice Grossman, M.D., chairman, offered a report on insurance. It proposed six categories of conditions that would replace the official nomenclature and statements of disability. These statements were edited, and the revised form was being submitted, along with the memorandum indicating the task force's recommendation that the statements be distributed to the district branches and to all interested parties in the Health Insurance Council. The Council recommended this procedure.

The task force was concerned with the problem of the all-inclusive release form signed by patients as part of their insurance contract negotiations. The task force expressed the hope that AMA might consider retracting its approval of the form unless the release of information is limited and conditional. Further, it was recommended that APA not approve any psychiatric or other medical form that contains such a blanket release of information to be signed by the patient. The Council concurred in this recommendation.

Whereas privilege and confidentiality were once considered inseparable, the task force realized that all of the reviewed statements only dealt with privilege and recommended that the Committee on Psychiatry and the Law and those others which appropriately deal with seeking improvement of the proposed Federal Code of Evidence try to get the additional protection regarding confidentiality into the Federal Code. The task force was hoping to modify a code of Public Law 92-255 in order to limit the information that would be released under the Patient Litigant Exception to Privilege, which would require judges to rule out many factors before releasing information about patients to the courts. The Council decided that this matter should be referred to the Committee on Psychiatry and the Law for its support and collaboration.

The task force submitted 18 recommendations at the fall committee meetings in October 1971 that would implement the principles and problems set forth in a position statement on privilege and confidentiality. It received no feedback from any source. It has edited and rewritten the position statement "Principles Governing Confidentiality and Disclosures to Third Parties." Since this had yet to be reviewed for the Council, the matter was to be carried over to its next meeting. The Council would then be able to determine whether the statement is ready for referral to the district branches.

The *Task Force on the Right to Treatment*, Bernard Diamond, M.D., chairman, expressed the belief that the right to treatment is and has been the most critical issue in American psychiatry and unanimously endorsed Judge Johnson's recent conclusion that "to deprive any citizen of his or her liberty upon the altruistic theory that the confinement is for humane therapeutic reasons and then fail to provide adequate treatment violates the very fundamentals of due process." The task force felt strongly that APA should recognize the need to add its authority to the common cause of those who, like Judge Johnson, have brought public, legal, and governmental attention to the degrading, demeaning, and antitherapeutic conditions that exist in some facilities for the mentally ill and the mentally retarded. It recommended that APA set its own minimal adequate standards for institutions and that it file an amicus curiae brief in the case of *Wyatt v. Stickney*. Further, it urged that APA offer its complete cooperation to Judge Johnson in any further hearings or consultations. The Council concurred with these recommendations.

The *Committee on Psychiatry and the Law*, Herbert E. Thomas, M.D., chairman, requested the privilege of appearing before the November meeting of the Assembly of District Branches in order to discuss the position statement on involuntary hospitalization (see March 1973 issue of the *Journal*). It wished to briefly state the changes proposed in accordance with recommendations of the committee from the Assembly of District Branches. Dr. Thomas hoped that he could head off any further move to completely redo this paper since it has been in the committee's hands for over three years; he said he believed any further procrastination would be a disservice to everyone concerned. The Council concurred in this request.

The committee had a lengthy discussion with Mr. Milton G. Rector of the National Council on Crime and Delinquency. It learned that the federal and state governments are about to proceed with an immense building program for correctional facilities. This, the committee felt, represents a waste of money at a time when the main professional effort has been to find alternatives to institutions. It was decided that efforts would be made during the next few months to formulate a statement that might be useful to the Council either as a position statement on or as a preamble to what might become a serious effort to review the role of the psychiatrist in the criminal justice process. The Council concurred and recommended that the committee be encouraged to pursue this interest in collaboration with any other APA committee that was interested.

The committee also met with Robert L. Sadoff, M.D., president of the American Academy of Psychiatry and the Law and a member of APA, in order to collaborate on plans made for a joint meeting in Atlanta, March 15–17, 1973. It was noted that Dr. Howard Rome would lend the additional support of the AMA Council on Mental Health.

Two items not covered at their meeting will be reviewed later by the committee members. These were the problem of diagnosis by mail and a request by Dr. Raymond W. Waggoner that the committee consider the matter of involuntary hospitalization in terms of certain problems that his ad hoc committee is currently attempting to work with.

Dr. Thomas reported that, since the fall meeting terminated his chairmanship, he was anxious to see that the work of the committee continues without interruption. For example, one consultant has said that there are at least five areas in the American Bar Association where participation by APA would be most welcome. The Council, in recognition of the fact that Dr. Thomas has fulfilled two terms, requested concurrence of the Reference Committee in supporting the recommendation that Dr. Thomas be considered for continuation in this vital role. The Council, therefore, unanimously recommended that he be seriously considered for another three-year term.

The *Task Force on Religion and Psychiatry*, Abraham Franzblau, M.D., chairman, did not have any recommendations for the Council to act on. However, it has been involved in distributing the "Registry of the Providers of Psychiatric Services" to religious institutions.

The *Committee on Psychiatric Nursing*, Harvey L.P. Res-

nik, M.D., chairman, asked that its name be changed to the "Committee in Liaison with the American Nurses' Association." The Council did not recommend the new name in that the word "liaison" would not attach sufficient significance to the purpose of this committee; furthermore, liaison with the American Nurses' Association (ANA) alone would exclude other nursing organizations.

The committee, having met with Dr. Hammersley, recommended that APA record its disappointment that psychiatry was not represented in the AMA-ANA Joint Practice Committee Report; this report should be ratified as soon as possible. The Council found no fault with this recommendation and relied upon its staff representative, Dr. Hammersley, for his concurrence.

The committee, having been charged by the Council to further justify a consumer committee, related that a consumer committee is needed to inform and advise APA on matters relating to the delivery of psychiatric care as seen by those who receive services. The committee went on to request that the group not exceed 11 members; that its composition should represent parent groups, patient groups, the National Association for Mental Health, the Narcotic Addiction Rehabilitation Commission, Recovery Incorporated, Alcoholics Anonymous, Synanon, Parent-Teacher Associations, the United Auto Workers, the insurance industry, management, and prisoners; and that it should reflect the various sexual, ethnic, and geographic elements of the population. It recommended that a special task force be appointed by APA to study this proposal further. The Council concurred and is prepared to establish such a task force if doing so appears not to fall within the realm of any other council.

Dr. Resnik announced that he would be resigning at the end of the year because of a new job assignment and expressed the hope of the committee that the new chairman be selected from among its membership in order to maintain continuity. The entire issue of the succession of chairmen of committees, councils, and task forces was discussed at length with the following recommendations resulting:

1. The committee recommended that a successor be appointed from its midst, and the Council concurred.

2. The committee recommended that a policy be fixed within APA that replacements for chairmanships of committees, councils, and task forces be filled from nominations within the membership of the same, subject to the discretion of the President. Under circumstances when concurrence was not obtained and it was necessary to introduce others for a chairmanship, this should be accomplished with the concurrence of the Executive Committee. The Council felt that this recommendation lay entirely within the jurisdiction of the President.

The *Committee on Liaison with the American College of Physicians* (ACP), Charles P. Neumann, M.D., chairman, formulated plans for the presentation of two programs—one at the APA annual meeting and one at the ACP annual meeting in 1973. Expenses for the APA annual meeting in Honolulu will be kept to a minimum by utilizing either people from the State of Hawaii or from the west coast. The committee predicted that only the travel expenses and honoraria for two faculty physicians will be necessary. The Council approved the two programs, as well as the expenses necessary to implement them.

The committee also met with the Committee on Psychiatry and Medical Practice to learn of their plans for the 11th Colloquium on the Postgraduate Teaching of Psychiatry. The committee asked to send one observer; the Council recommended approval.

The committee discussed the abolition of the internship and expressed its profound concern that as a consequence psychiatry would lose its identity with medicine.

The *Committee on Psychiatry and Social Work*, Joseph B. Parker, M.D., chairman, recommended that it be disbanded. In its place it recommended that a task force in collaboration with other medical and nonmedical professions be developed. The Council concurred in the recommendation that the committee be discontinued; it will study the recommendation for a replacement.

The *Committee on Rehabilitation*, Nyla J. Cole, M.D., chairwoman, was ambivalent about whether or not it should be continued. In the event that the Council recommends discontinuation, the committee expressed the desire that advocacy for rehabilitation be assumed by some member of the Council. The committee expressed three areas of concern:

1. What goes on in medical school education regarding rehabilitation, and how does one encourage medical schools to include some teaching on rehabilitation in the department of psychiatry?

2. Continued effort should be made to include rehabilitation in the core curriculum.

3. There should be some device to maintain a general commitment to cross education in rehabilitation.

The Council decided to discontinue the committee and will determine later whether there is a need to create a task force for any specific issue.

The Council on Internal Organization

JACK A. WOLFORD, M.D., CHAIRMAN

THE COUNCIL ON INTERNAL ORGANIZATION met October 11–14, 1972, in Washington, D.C. Dr. Alyce C. Gullattee and Dr. Thomas Conklin served as consultants. Dr. James Stevenson, a Falk Fellow, met with the Council; Dr. Karen Preis, the second Falk Fellow, met with the Committee on Program; and Dr. Bernard Fisher, the third Falk Fellow, met with the Committee on Public Information. Dr. Harry A. Brunt and Dr. John R. Saunders represented the Board of Trustees and Dr. Walter E. Barton represented APA staff.

As requested last October, Donald W. Hammersley, M.D., reported on the state of *Hospital & Community Psychiatry* so that a decision might be made regarding offering the journal as a prerequisite of membership. He felt that the editorial staff had broadened the content of the journal but were worried about the shift that might be required to "satisfy" a great many more psychiatrists reading the journal. Dr. Hammersley pointed out

that discussing the question of *H&CP* as a perquisite at this time was largely academic since monies were not available. It therefore appeared that in view of the current economic situation it was best to defer any decision regarding *Hospital & Community Psychiatry*. In general the Council was impressed by the continued improvement of the journal.

Dr. Hammersley reported that the 24th Institute on Hospital & Community Psychiatry, held in St. Louis, Mo., was a success. The next meeting will be at the Americana Hotel in Miami, Fla., September 17–20, 1973. The planning and staff work will be done under the direction of Henry Work, M.D. The Council members extended their thanks to Dr. Hammersley for his work over the years in relation to the Institute on Hospital & Community Psychiatry.

The Council discussed the Task Force of Residents at length with the Council on Medical Education and Career Development and the residents. It expressed willingness to assume responsibility for this task force if desired.

During the meeting, the Council members toured APA headquarters and talked with people in each section. The visit to the offices of the *Journal* resulted in an informative discussion with Dr. Francis J. Braceland. While the Council members were impressed, their ignorance of the "internal organizations" was disturbing. They requested Dr. Barton and the staff to conduct a day-long session regarding the matters of APA about which they should be knowledgeable and concerned. This was particularly important in light of our auditors' report recommending that a year's study be given to: 1) the computerization of fiscal records into a single accounting system, and 2) the appointment of a Deputy for Business Affairs or Management to parallel the duties of the current Deputy Medical Director.

Hayden H. Donahue, M.D., chairman, *Committee on Grants and Awards*, talked with the Council about the various awards and honorary lectures. The committee recommended changes in the Operations Manual and is investigating a new award.

The *Committee on Conventions*, Alexander Simon, M.D., chairman, made recommendations for the 1973 annual meeting in Hawaii. The Council commended the committee members for their excellent work.

The *Committee on Program*, Melvin Sabshin, M.D., chairman, brought the Council up to date. As usual, this committee has planned an excellent program for the 1973 annual meeting, and the Council commended its members for their work.

Dr. Sabshin also pointed out that the AMA currently has an APA "Representative for Program" in its Psychiatry Section, the representative being Dr. H. Keith H. Brodie. The Council urged that the committee make a recommendation to continue this position when Dr. Brodie's term expires.

The *Task Force on Arrangements*, George Schnack, M.D., chairman, reported that it was working on arrangements for the 1973 annual meeting.

The *Committee on Member Insurance and Retirement Plans*, Chester Trent, M.D., chairman, was congratulated for its long and tireless effort to develop a new physicians' liability policy, which is now in effect. In keeping with this a recommendation was made to the APA President that he appoint a Loss Control Committee.

The Council accepted the recommendation of the committee that it does not appear to be necessary to survey the 780 members who have had liability experience.

The APA retirement plans were a topic of discussion, and the duties of the Trustees of the APA Retirement Plan were reviewed. The Council recommended that various recommendations of the committee concerning safeguards be implemented, including one stating that all changes in the by-laws requested by the administrator of the plan should be independently reviewed by the Association's attorney and the medical director before being presented to the Committee on Insurance or the Executive Committee. The independent review of the performance of the plan by the consultant to the Committee on Insurance was lauded.

The responsibilities of the Trustees of the APA Retirement Plan seemed sound, and the Council urged acceptance. In essence they are designed for the ongoing evaluation of performance in conjunction with the consultant to the committee and with the APA treasurer. Further, it was requested that Mr. Murray W. Latimer's report, in a form interpreted by the chairman of the committee, be made available to participating members and to any potential new members. It was also recommended that the annual report be furnished to the participating members. The Council also concurred in the recommendation concerning an adequate annual audit. An assessment of the marketing activities and their adequacy as carried out by the administrator was considered to be a sound recommendation.

The committee would like to search out a "broker of record" to reevaluate APA insurance programs, and the Council concurred with this plan.

The *Committee on Public Information*, Zigmond M. Lebensohn, M.D., chairman, has selected a winner of the Robert T. Morse Writer's Award. The winner will be announced at the Convocation of the 1973 annual meeting. The committee was considering the possibility of a public attitude survey concerning psychiatry. Further study is needed, with a review of the literature, design study, and consultation with the Council on Research and Development.

The committee recommended that no further statements by APA regarding positions of great responsibility in our society and mental illness are indicated at this time.

The *Psychiatric Glossary* was reviewed; it was recommended that it be retained in its present form for now. APA sponsorship of an educational film series is being considered by the committee.

The *McGavin Award Selection Board*, Marshall D. Schechter, M.D., chairman, announced that it will have a selection for an award at the annual meeting.

The *Vestermark Prize Board*, William Malamud, M.D., chairman, met and selected a recipient for this award, which will be announced at the Convocation.

The *Isaac Ray Award Board*, Donald H. Russell, M.D., chairman, reported that it was selecting a recipient for this award. The board was in the process of looking for more money. The Council expressed the hope that the entire association would back this outstanding award honoring one of APA's founders and that support money could be found.

The *Manfred S. Guttmacher Award Board*, Jonas R. Rappeport, M.D., chairman, and the *Hofheimer Prize Board*, Robert A. Cohen M.D., chairman, were in the process of selecting recipients. The winners will be announced at the Convocation of the 1973 annual meeting.

The *House Committee*, Marvin Adland, M.D., chairman, reported that all is well with APA property.

The last report was from one of the Falk Fellows, James M. Stevenson, M.D., which the Council accepted with thanks. Dr. Stevenson was a participant throughout the meeting, and from his report appeared to have developed greater insight into the organization and its complexities and functions. He supported the Falk Fellow program and its objectives. The Council was pleased that he saw its members as being egalitarian in their reception of him. Dr. Stevenson strongly supported resident participation at all levels of APA.

The Council has been planning a meeting in Washington,

D.C., March 30–31, to study the APA's organization and function and other matters concerning future needs.

The Council thanked APA staff, and particularly Dr. Walter Barton, for their tireless devotion.

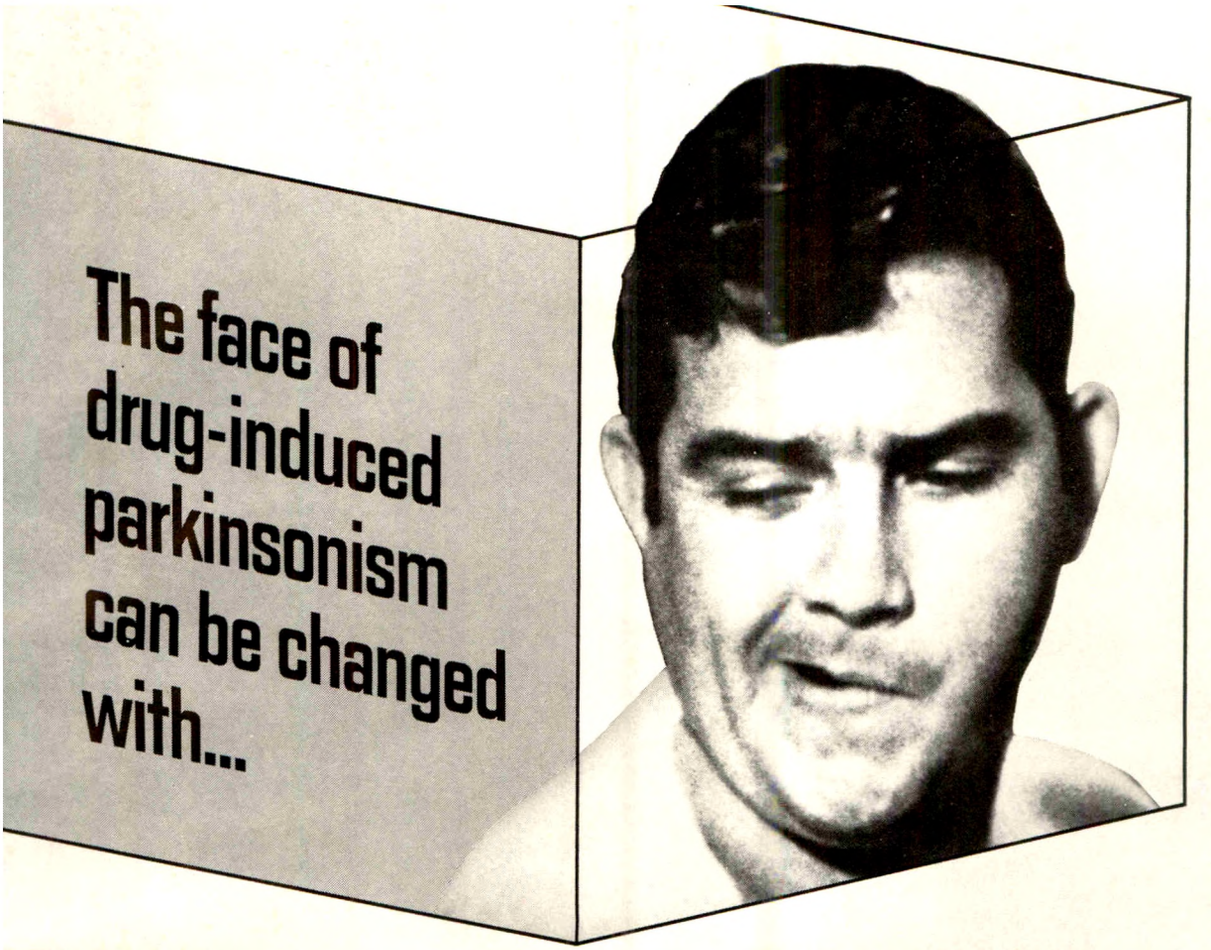
The Assembly of District Branches

Committee on Divisional Meetings. One of the most successful APA divisional meetings was held in San Diego, Calif., October 5–8, 1972. Concerned with the theme "Psychiatrists and the Future," the program was planned in order to involve practicing psychiatrists, as well as those in training. The meeting was well attended and drew a great deal of approbation. In October 1973, Area III will hold a divisional meeting in Williamsburg, Va. This meeting will coincide with the centennial of Eastern State Hospital, located in that city, and is planned to be a fitting commemorative.

The *Commission on Future Planning of the Assembly*, which is currently the Assembly's most active committee, is concerned with all matters related to the overall organization of the Assembly, as well as with considering procedures for making it a more effective body. During the past year, it has considered the effect the 1973 annual meeting in Hawaii will have on the Assembly and has made plans to take further advantage of this setting.

The commission has restudied the matter of Canadian members and has suggested a renewed APA-CPA committee. Currently, the commission has no recommendations for a new class of membership.

The commission has also been active in urging the area councils to develop mechanisms for handling resolutions; much of this has been effected. Recently it proposed that members of the Assembly be appointed to APA councils. The Reference Committee considered and has approved this concept in principle. It has also been planned that members of the Executive Committee of the Assembly be appointed as liaison members of the APA councils. Through the commission's efforts, material coming from the Reference Committee and the Board of Trustees has been sent to the Assembly for consideration before final approval.



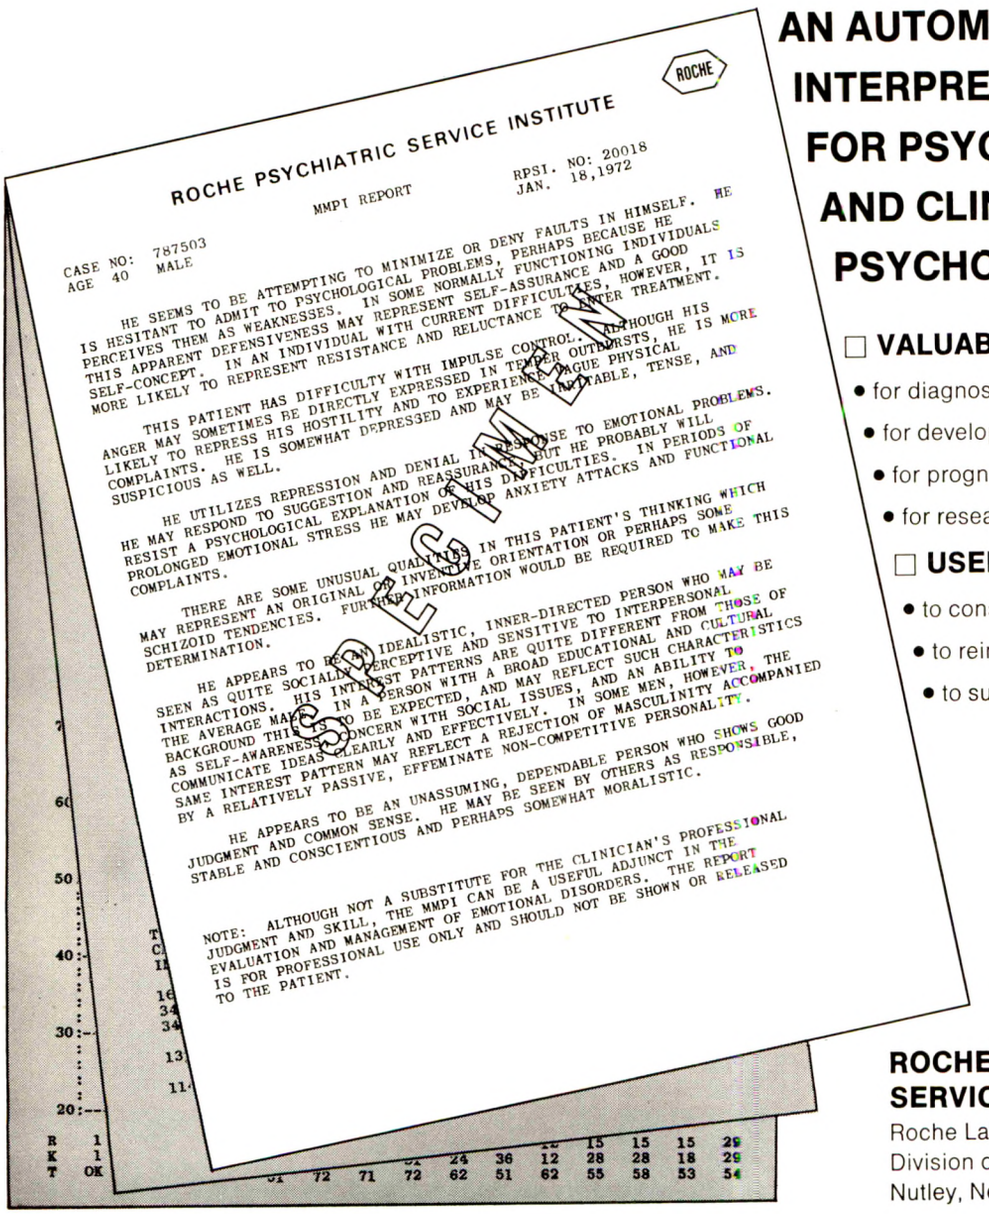
The *Committee on Liaison Between the Assembly and NIMH* has met periodically with representatives from the Division of Mental Health Services of NIMH. In addition it has urged that area councils begin to assume greater responsibilities in evaluating mental health programs in their respective regions.

Many district branches have been sending their newsletters to the regional office in their area, and the committee has assisted in distributing "News from NIMH" to all district branches. The committee is responsible for planning part of the Assembly fall program, and in 1972 it once again had Dr. Bertrand Brown and his staff present to discuss NIMH activities.

The district branches have been involved in major recruitment efforts to induce members-in-training to become part of APA; the *Committee on Membership* has actively supported this drive, which is beginning to bear fruit in the number of residents who have applied and been accepted for membership. The committee has been urging the district branches to advance these members as rapidly as possible and to use them in committee functions within the district branches. The committee has also been concerned about the transfer of membership from one district branch to another and is actively working on this problem.

The *Task Force on Delivery of Mental Health Services* has been discussing material related to peer review, national health insurance, and various statements from such groups within APA as the Committee for Concerned Psychiatrists. The task force has commented on many of the reports from committees and councils and has been helpful to the Assembly in organizing its thinking around these major issues.

The *Task Force to Define the Nature, Scope, and/or Areas of Competence of the Specialty of Psychiatry* met for the first time in November 1972. It is charged with defining the identity of psychiatry and with differentiating psychiatry from other disciplines in the mental health field. After reviewing the APA pamphlet "What Is a Psychiatrist?" the task force decided that it was obsolete. At its original meeting the task force defined its role and elaborated questions to be discussed. It has made plans to meet in February 1973 to further its activities and to make plans for the future. The work of the task force ties in with other APA concerns about the specialty of psychiatry and the best way to represent it to the members, to other professions, and to the public.



AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally: **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

a new annual series

PSYCHOANALYSIS AND CONTEMPORARY SCIENCE

An Annual of Integrative and Interdisciplinary Studies

Volume I: Edited by Robert R. Holt and Emanuel Peterfreund
Volume II: Edited by Benjamin B. Rubinstein

Two pathbreaking volumes that should stimulate further interaction between psychoanalysis and contemporary sciences to their mutual benefit. The contributors, who represent many different branches of science, discuss the question of psychoanalysis itself—what kind of science it is or should aspire to be.

Volume I contains 15 papers by 21 distinguished scientists and deals with general theoretical issues, psycholinguistic problems, developmental issues, clinical and quantitative approaches, psychohistory, and psychobiography.
1972 $14.95

Volume II contains 19 original papers which analyze new perspectives on psychoanalysis, clinical psychoanalysis, approaches to the problem of development, clinical-experimental studies, models derived from information-processing theory, and issues in the philosophy of psychoanalysis. Included is a discussion of "The Logic of Explanation in Psychoanalysis" by Michael Sherwood.
1973 $14.95

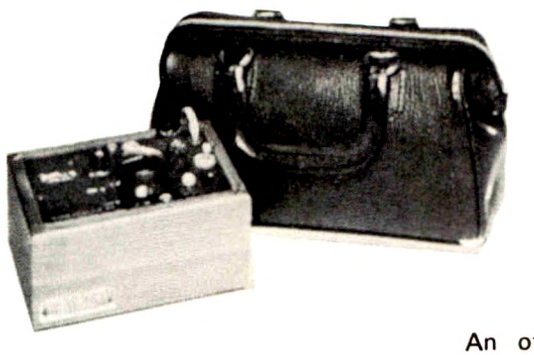
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

DEPARTMENT OF HEALTH
PROVINCE OF NEWFOUNDLAND
CANADA

PSYCHIATRISTS

Two psychiatrists required as full time consultants in the Division of Mental Health Services, St. John's. One position is in the forensic-correctional field and the other in the disorders of children.

These are challenging positions with opportunities to provide consultation in program development in a wide range of services in voluntary agencies, hospitals, educational settings and government departments. There is a possibility, also, for involvement in clinical work, teaching and research.

Salary is negotiable.

Full public service benefits apply with generous annual and sick leave with pay, provincial statutory holidays and contributory pension plan. Financial assistance towards relocation is available.

Applications and/or requests for further information should be addressed to:

C. H. POTTLE, M.D., F.R.C.P. (C), F.A.C.P.
Director
Mental Health Services
Government Building
Harvey Road
St. John's, Nfld.
Canada

PSYCHIATRIC RESIDENTS

Opening for psychiatric residents in accredited General Hospital, adult, adolescent and child psychiatric services with in- and outpatient departments. Comprehensive didactic program by members of the staff. Salary according to qualifications. These residencies are approved by the University and recognized as part of the McGill University Diploma Course.

Please apply to:

S. H. Knox,
Executive Director,
Lakeshore General Hospital,
Pointe Claire, P.Q.

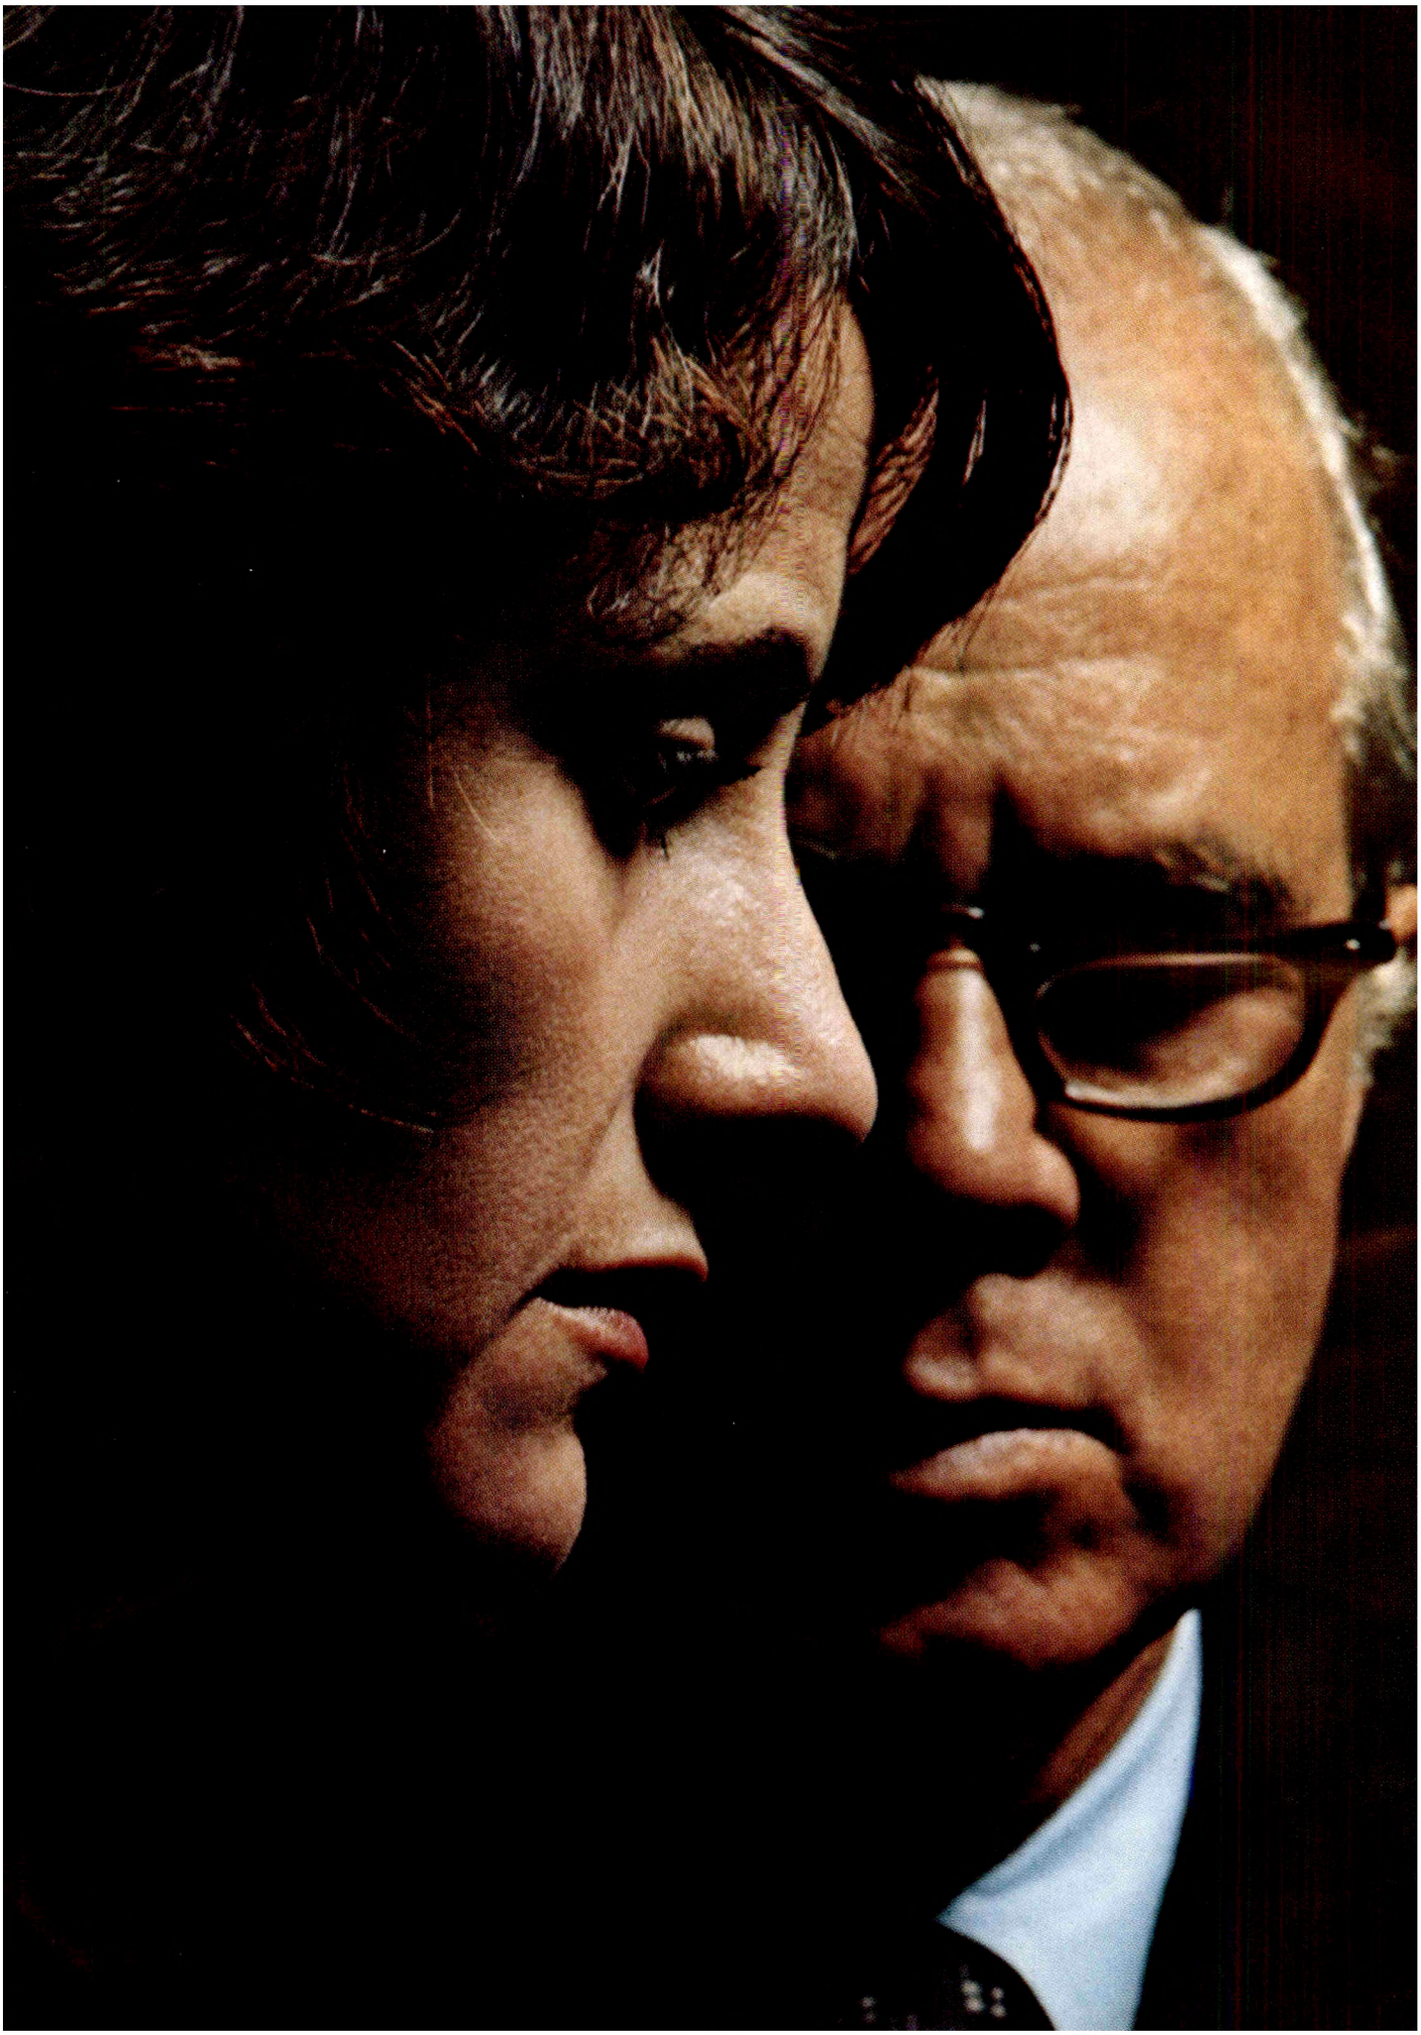
UNIQUE-NESS:

In People & at the Lutheran Hospital Psychiatric Care Unit

Providing complete psychiatric care in a general hospital setting with special emphasis on disorders of adolescence.

Lutheran Hospital of Milwaukee, Inc.

Basil Jackson, M.D., D.P.M., M.Th., F.A.C.P.
Chairman, Department of Psychiatry
2200 W. Kilbourn Ave. Milwaukee, Wisc. 53233



Child Psychiatry Residencies

New, Board Approved, Child Psychiatry Residencies offered in an innovative, established clinical program. Community Child Psychiatry, Day Treatment, Outpatient and Residential Treatment offer opportunities for a variety of treatment techniques. Crisis intervention ("life-space" interview); behavioral therapy, pharmacotherapy; individual, group and family treatment methods; dynamic, social and developmental psychiatry taught. Learning by independent study, seminars, supervised experiences. Multi-disciplinary staff including; six child psychiatrists, pediatrician, pediatric neurologist, psychologist, social workers, special education teachers, speech therapists, occupational therapist, recreational therapists, etc. Program affiliated with the University of Michigan and a variety of clinical settings including; community mental health centers, guidance clinics, etc. Salaries negotiable.

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

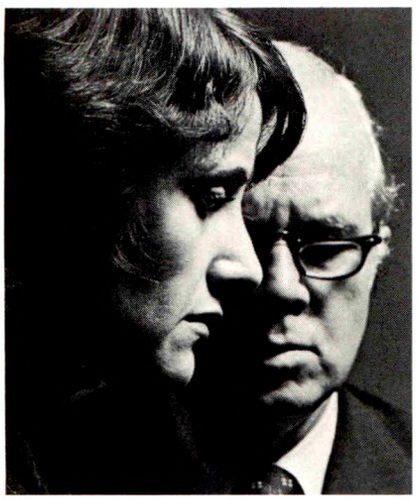
MERCK SHARP & DOHME



For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety
or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; pregnancy; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction. Not recommended in children.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, narrow-angle glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage.
The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant drug. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL has seemed to reduce the likelihood of this effect.
Supervise closely and carefully adjust dosage when given with anticholinergic agents and sympathomimetic drugs.
The drug may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards of therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible.
Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonos, oculogyric crises, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reaction); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galac-

orrhea, disturbances of menstrual cycle); altered cerebrospinal luid proteins; paradoxical excitement; ECG abnormalities quinidine-like effect); reactivation of psychotic processes; atatonic-like states; autonomic reactions, such as dryness of he mouth, headache, nausea, vomiting, constipation, obstipaion, urinary frequency, blurred vision, nasal congestion, and a hange in pulse rate; hypnotic effects; pigmentary retinopathy; orneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias pancytopenia, thrombocytopenic purpura, leukopenia, agranuocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; ncoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

For more detailed information, consult your MSD Representative or see full Prescribing Information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Act vity appropriate in degree and duration to environmental stimuli.

Performance — vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.

Anxiety Amelioration — in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

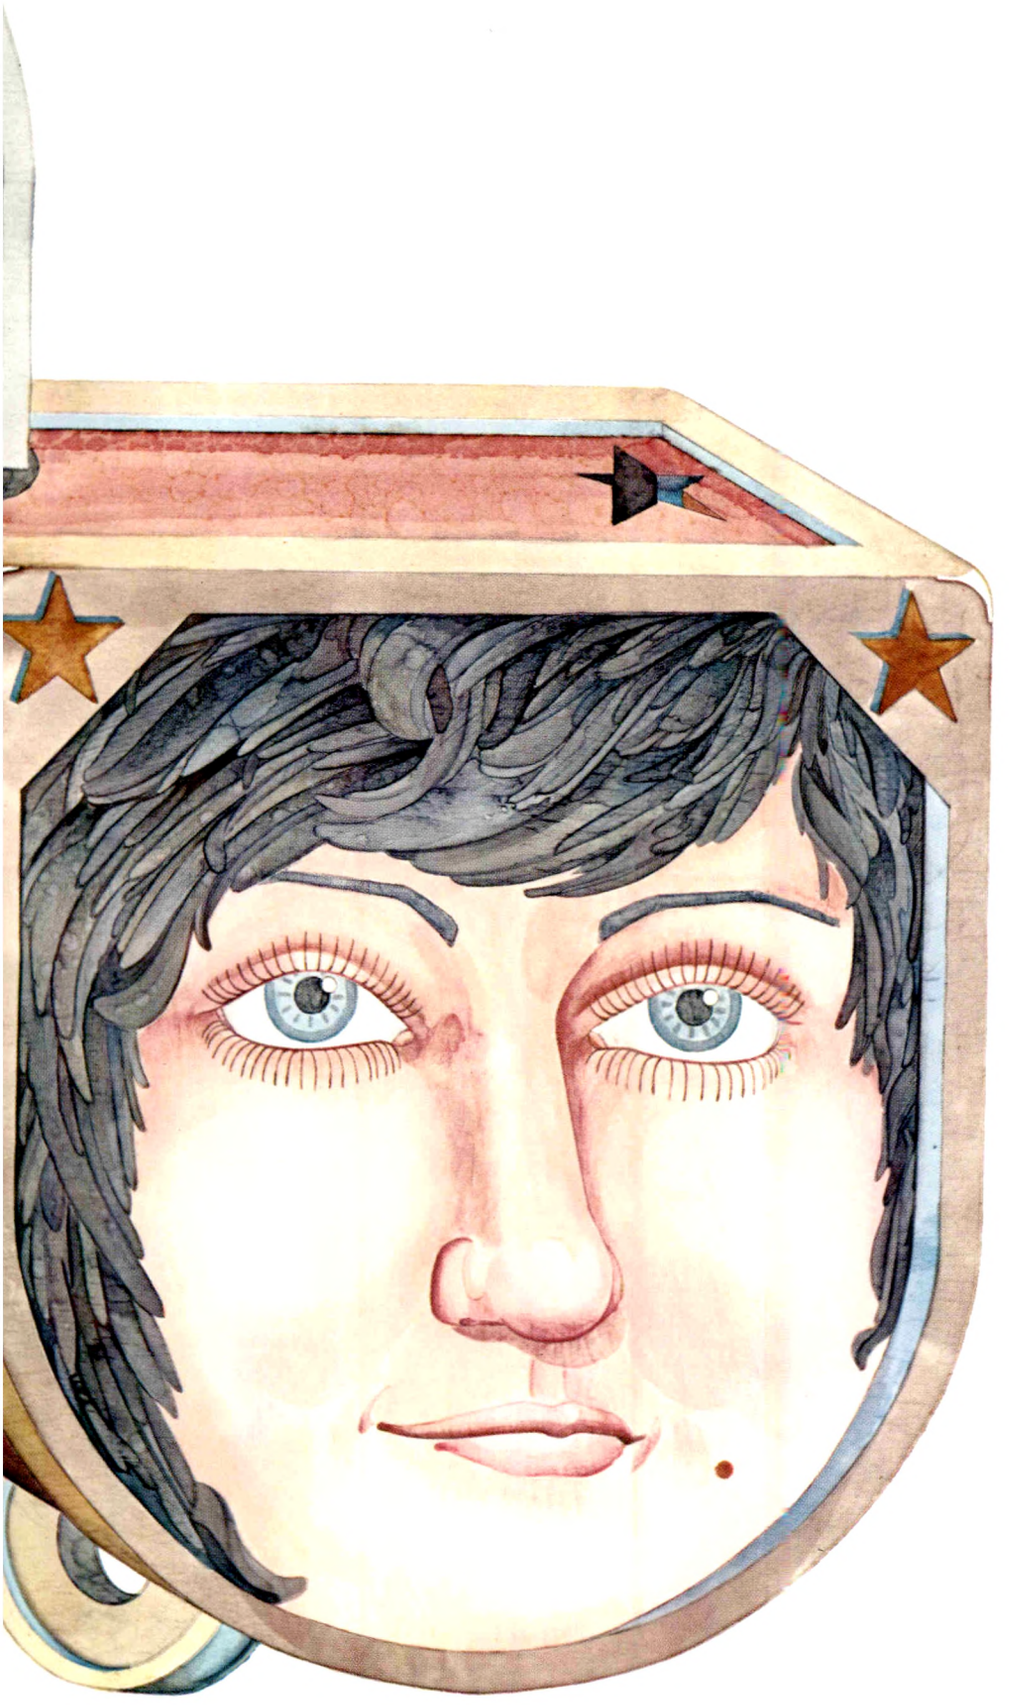
Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.



As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

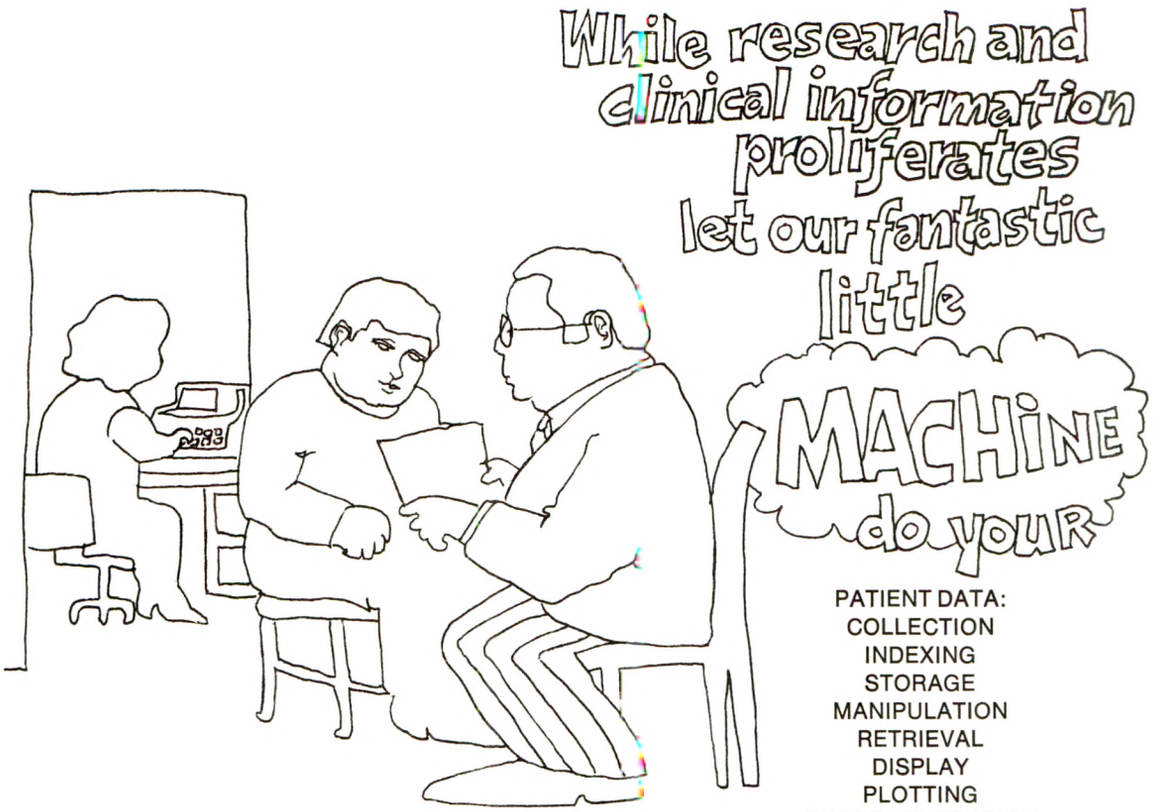
This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.



Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

. . . If your activities depend upon the acquisition, organization, maintenance, recall and regeneration of medical data and information . . .

Biomedimation Corporation can provide qualified prospects with trial use of a convenient, low cost and reliable desk-top medical information and patient data management service.

You may subscribe to any or all of these related services:

DATABASE MANAGEMENT—Automated collection, safe storage, manipulation, display and analysis of data and information. Automated information indexing, storage and retrieval. Document reference retrieval.

NETWORK MANAGEMENT—Access to the database from one or more locations.

GRAPHICS MANAGEMENT—Automated letter writing (replaces your MT/ST or MC/ST), journal article drafting, text editing, plotting and chart generation.

EXPERT CONSULTATION—Biostatistical, experimental design, forms design, and information indexing support; and personnel training.

IMPLEMENTATION OF THE PROBLEM ORIENTED MEDICAL RECORD—We can also be of material assistance if you are planning a **PSRO** or a **HMO.**

Biomedimation's services are as reliable and as easy to install and maintain as your office typewriter. They are more convenient to use than a typewriter, a time-sharing terminal or a batch processing computer.

Data collection, transcription and indexing errors are dampened to the level that meets your specific requirements at data entry.

Sensitive data and information are always absolutely secure. Retrieval and display of data and information, visually and/or in hard copy, is virtually unlimited. All source entries are instantly available, always.

At the conclusion of a trial use period, we believe you will agree that Biomedimation's services satisfy your needs at less true cost . . . at any level of activity, under any time constraints, at any level of confidentiality, and to a greater degree of satisfaction at every level of human involvement.

Biomedimation will establish these facts to your satisfaction by providing you with a trial use period.

For additional information, and to schedule a presentation, demonstration and trial usage, in the continental United States and the Canadian border areas—Telephone or write:

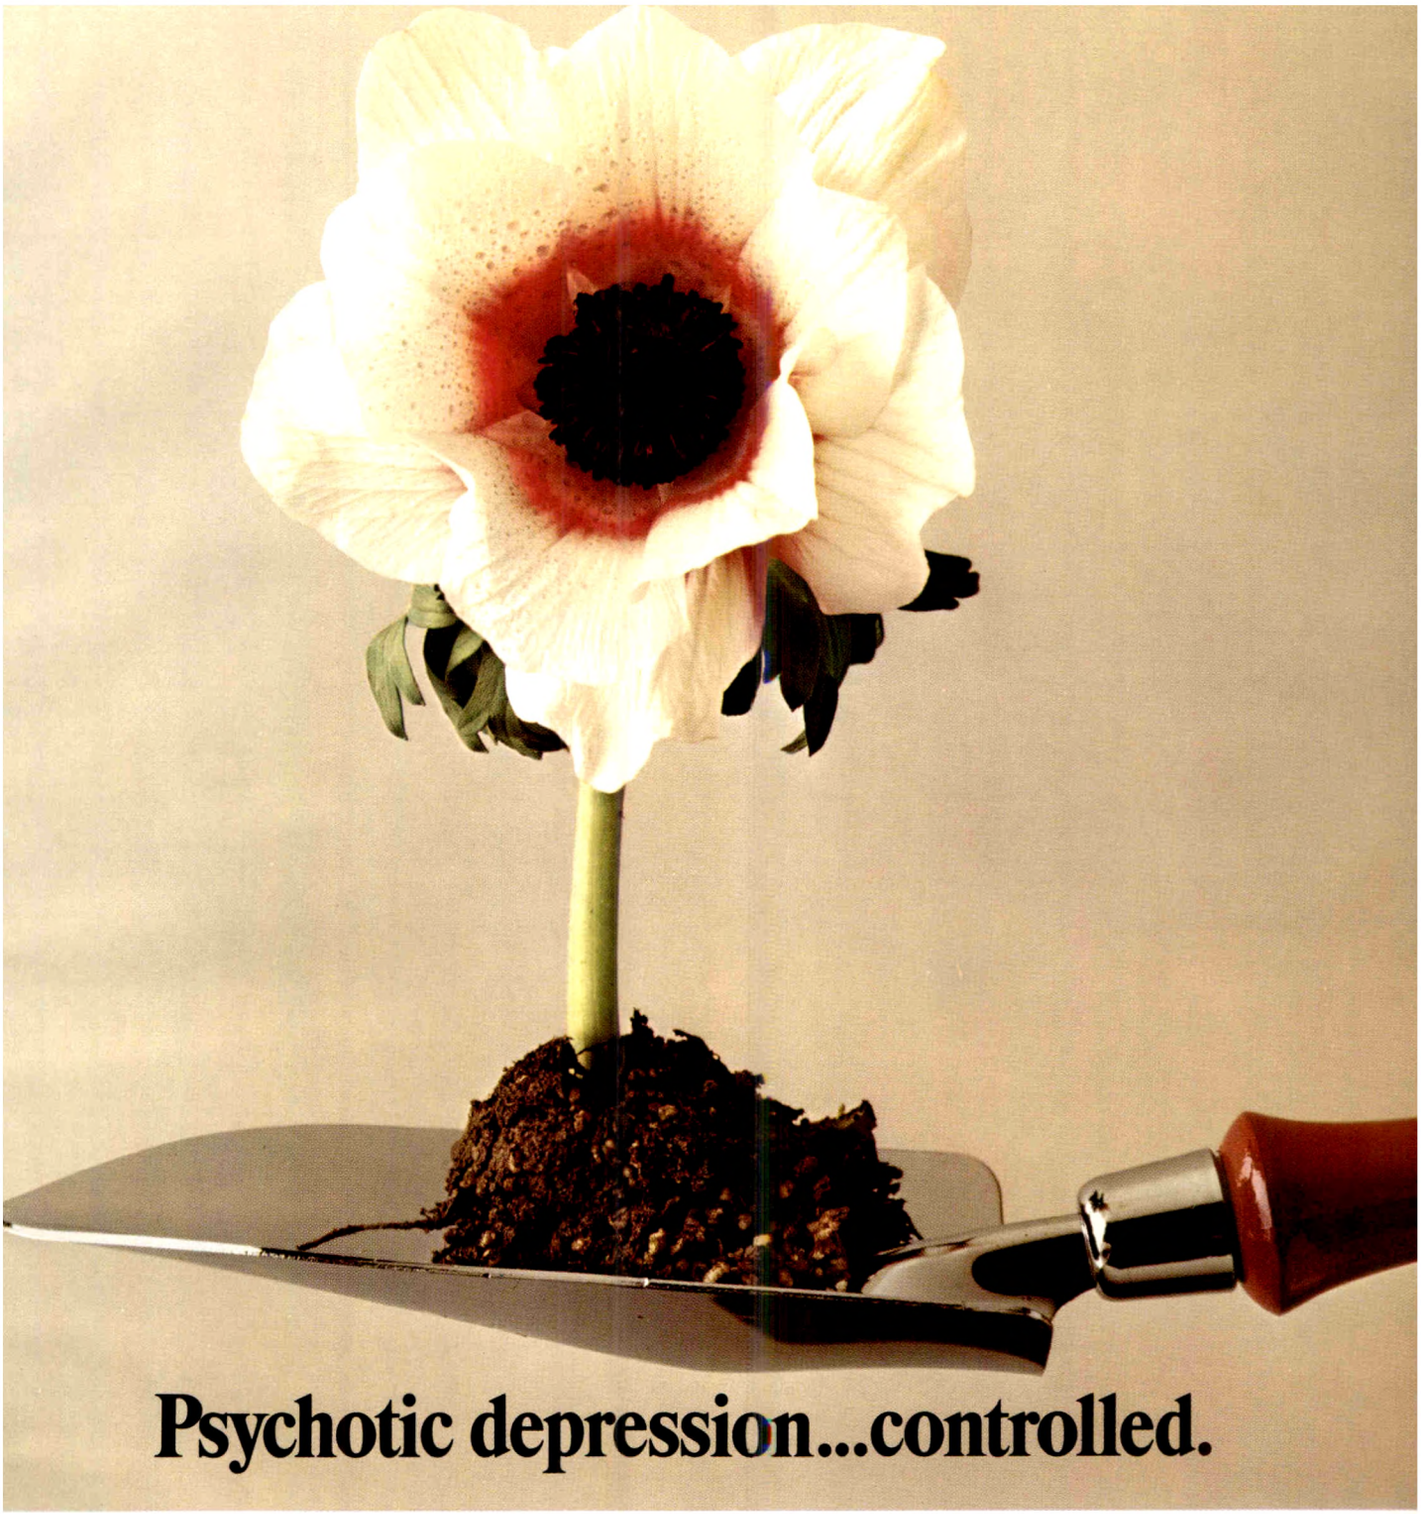
An applied Technology Service Company

Navane (thiothixene) helps reduce the intensity and frequency of acute psychotic symptoms. With Navane, confusion, disorientation and other manifestations of acute psychosis may be controlled. And, as acute symptomatology decreases, the patient may be better able to readjust to therapeutic, family and community relationships and responsibilities. Navane...an effective anti-psychotic for acute psychosis.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017



Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg., 2 mg., 5 mg., 10 mg. Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

to help control psychotic behavior

For prescribing information, including adverse reactions and contraindications, please see last page of this advertisement.

Psychotic depression...controlled.

Navane (thiothixene) helps reduce the intensity and frequency of depression as manifested in psychotic disorders. Mental and motor retardation may be replaced by an increasing interest in self and environment and a return to productive activity. Severe mood disorders may be relieved to encourage cooperation with therapy and daily routine. Navane...an effective anti-psychotic.

ROERIG Pfizer

Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg., 2 mg., 5 mg., 10 mg. Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

to help control psychotic depression

For prescribing information, including adverse reactions and contraindications, please see following page.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg.
Concentrate: 5 mg./cc.
Intramuscular: 2 mg./cc.

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg.
(thiothixene hydrochloride)
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the midlateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration because safe conditions for its use have not been established.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Usage in children under 12 years of age is not recommended.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of behavior is desirable, the intramuscular form of Navane (thiothixene hydrochloride) may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg. of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg./day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg. three times daily. If indicated, a subsequent increase to 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. daily. If indicated, an increase to 60 mg./day total daily dose is often effective. Exceeding a total daily dose of 60 mg. rarely increases the beneficial response.

Some patients have been successfully maintained on once-a-day Navane (thiothixene) therapy.

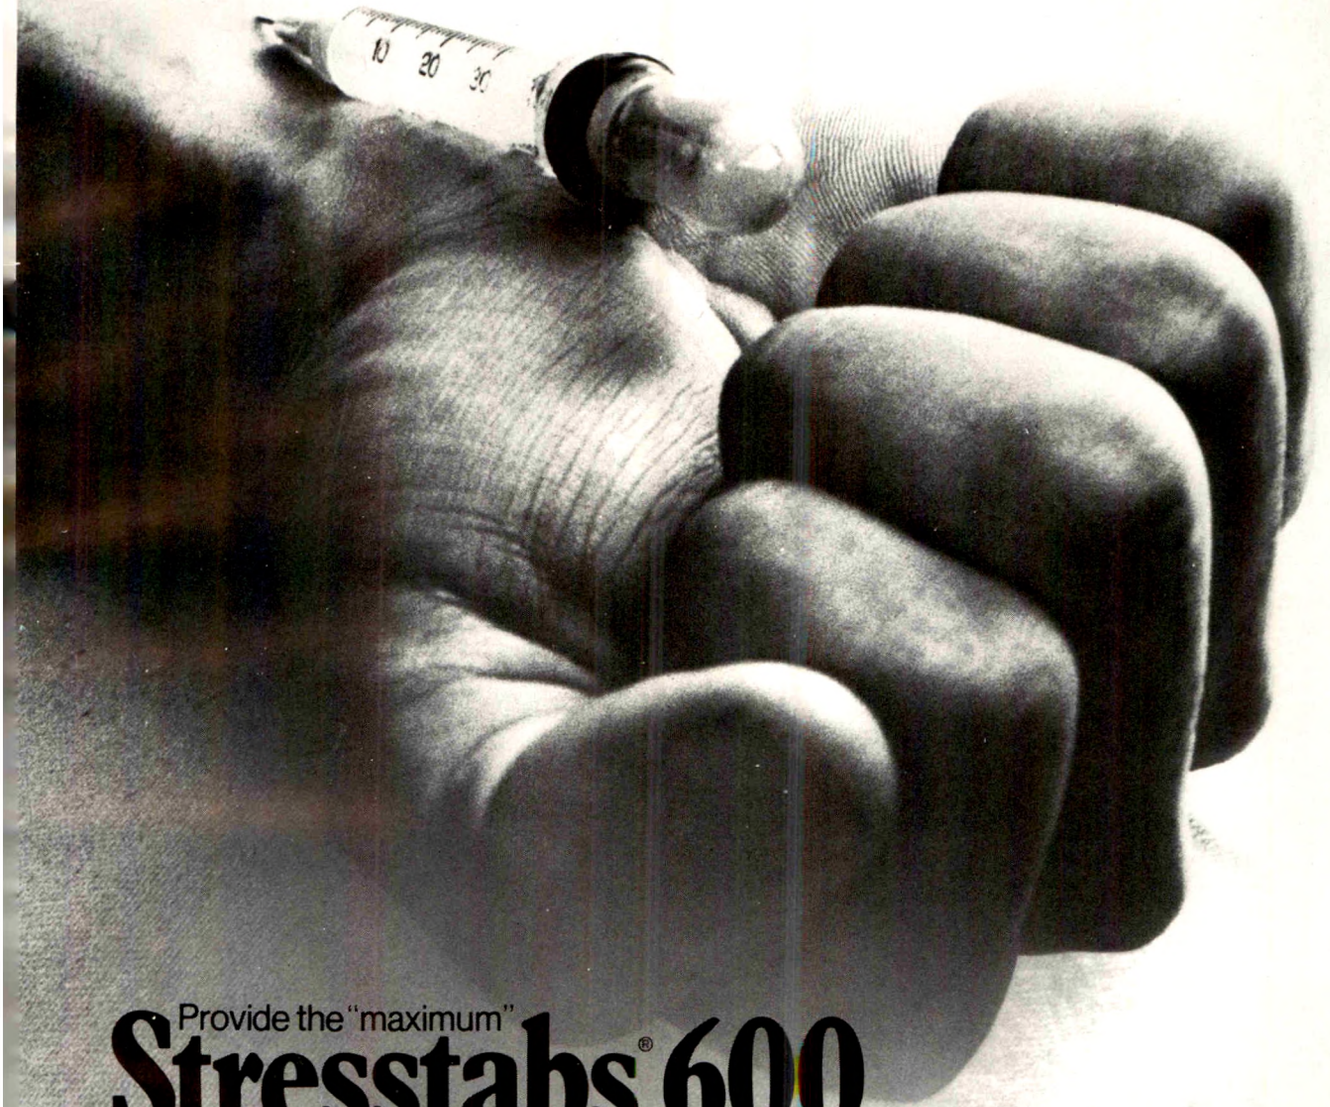
Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.



How Supplied. Navane (thiothixene) is available as capsules containing 1 mg., 2 mg., 5 mg., and 10 mg. in bottles of 100 and 1,000.

Navane (thiothixene hydrochloride) Concentrate is available in 120 cc. (4 oz.) bottles with an accompanying dropper calibrated at 2 mg., 4 mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each cc. contains thiothixene hydrochloride equivalent to 5 mg. of thiothixene. Contains alcohol, U.S.P. 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular Solution is available in a 2 cc. amber glass vial in packages of 10. Each cc. contains thiothixene hydrochloride equivalent to 2 mg. of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v.

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate) helps the patient respond in mild depression*

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)
TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established. Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension.

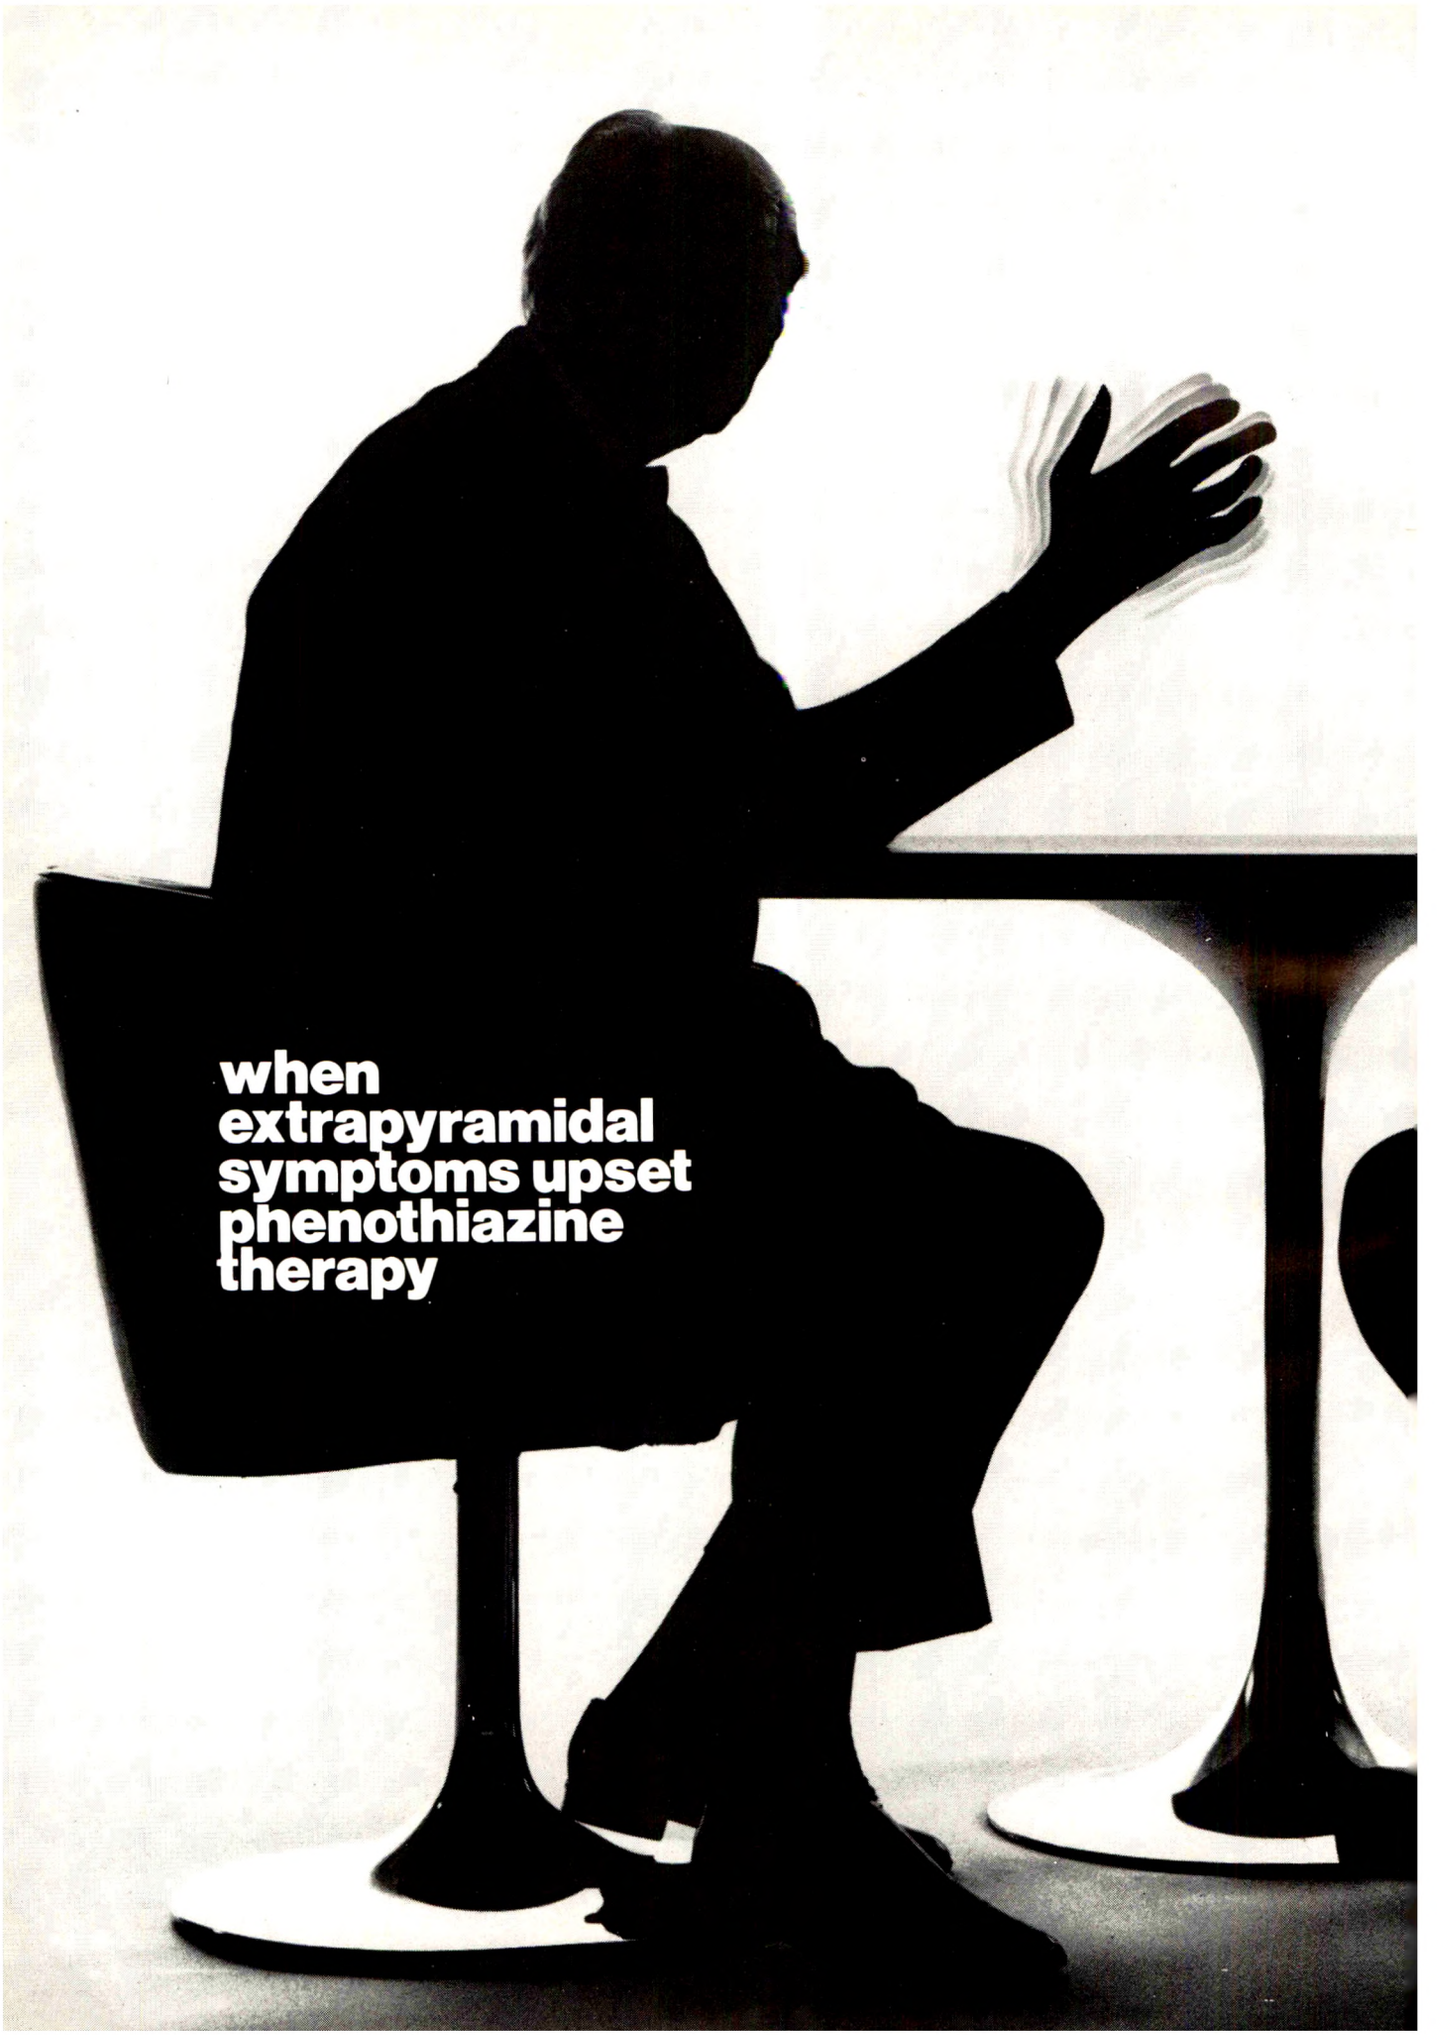
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

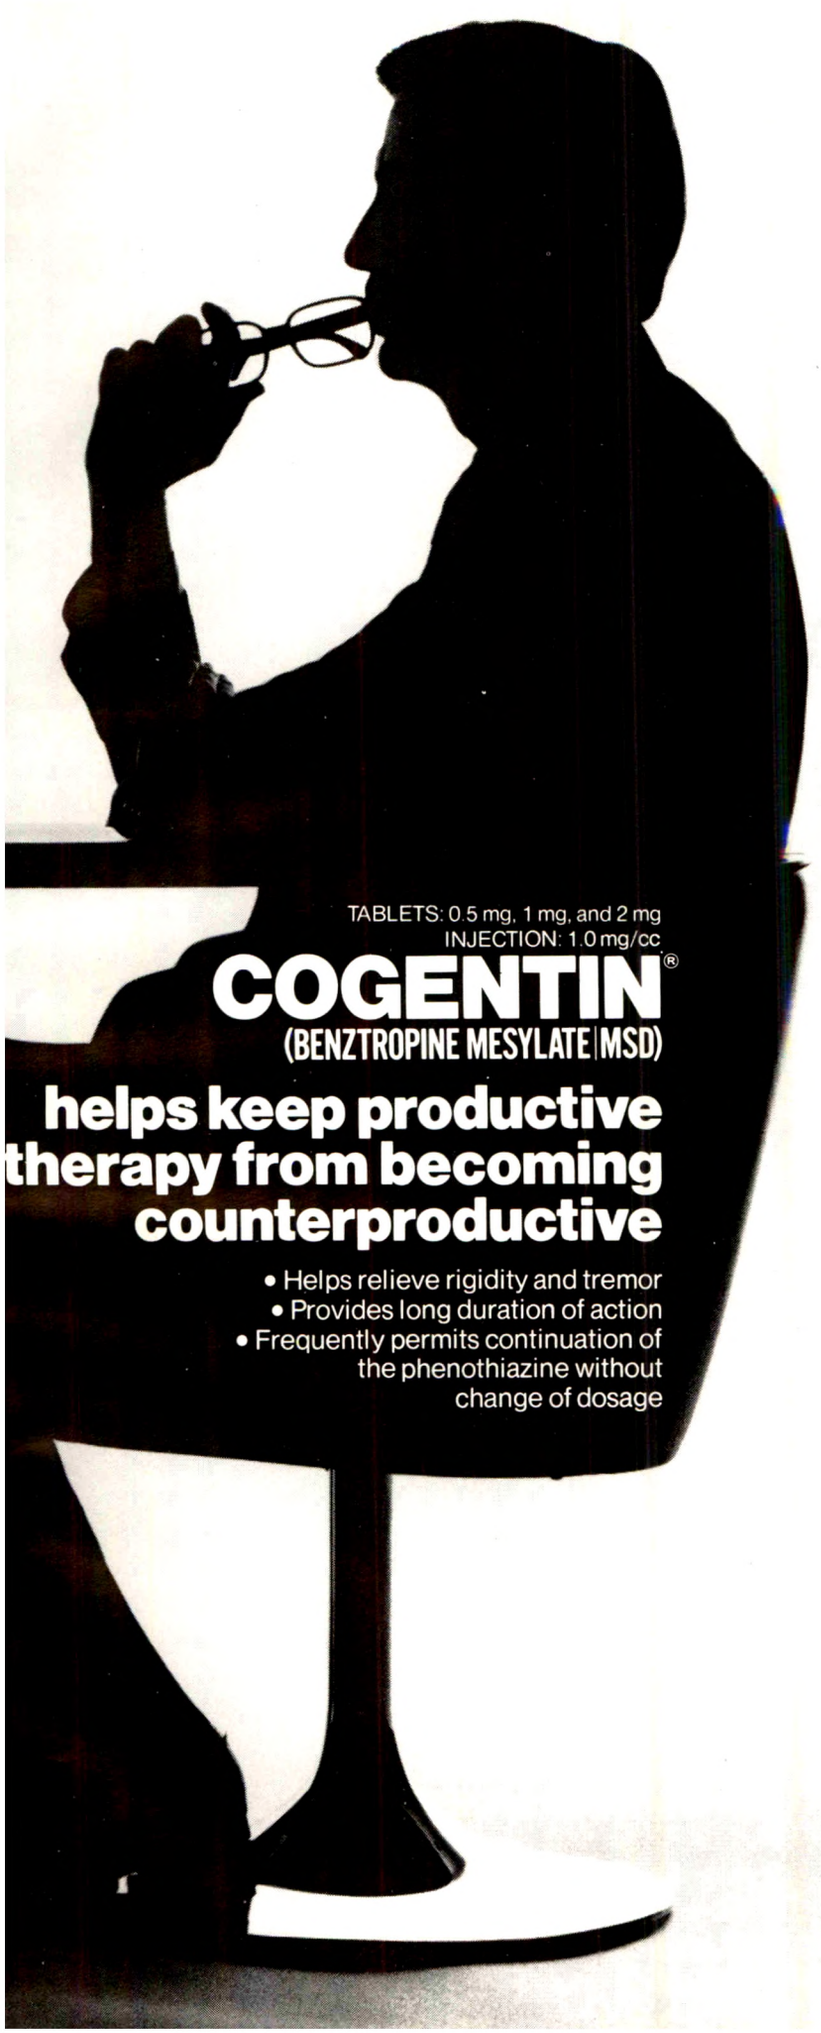
Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening.
Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.



DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.



HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.
Consult complete product literature before prescribing.

CIBA

when
extrapyramidal
symptoms upset
phenothiazine
therapy

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/cc

COGENTIN®
(BENZTROPINE MESYLATE|MSD)

helps keep productive therapy from becoming counterproductive

- Helps relieve rigidity and tremor
- Provides long duration of action
- Frequently permits continuation of the phenothiazine without change of dosage

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.
Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.
May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.
Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per cc, in 2-cc ampuls.

Three new JIS publications:

THE TREATMENT OF DRUG ABUSE — Programs, Problems, Prospects

AUTHORS: Raymond Glasscote, Jerome H. Jaffe, James N. Sussex, John Ball, Leon Brill

What can a community that wants to do something about a perceived drug abuse problem reasonably expect to get for its efforts? That is the question the authors undertook to answer through a field study that consisted of visits to nine programs operating more than forty facilities and components for various categories of persons who use drugs — mainly narcotics. They conclude that no single one of the presently available approaches can be expected to be successful with more than a small percentage of the drug-abusing population, and all approaches combined will have an "undoubtedly limited" effect. Rather than take a position for or against any particular treatment approach, they discuss the positive and negative features of each. A wealth of significant detail is provided about a number of well-known programs, with an objectivity that has been altogether too rare in this field. The authors set forth one reasonable sequence that might be followed by communities seeking to establish various drug treatment resources that will be appropriate for their particular needs.

CHILDREN AND MENTAL HEALTH CENTERS — Programs, Problems, Prospects

AUTHORS: Raymond Glasscote, Michael Fishman, Meyer Sonis

This tenth in a series of Joint Information Service field studies of mental health programs focuses on the efforts of federally assisted mental health centers to meet the needs of children and adolescents, both through direct treatment services and through consultation programs that seek to enhance the competence of numerous kinds of persons who have an important influence on the lives of children. Based on visits by the authors and consultants to eight outstanding programs, this volume also incorporates the findings of a questionnaire survey to all federally supported community mental health centers. It also provides a full but concise history of treatment efforts for young people in this country, and, most important, it sets forth a hypothetical comprehensive program that is broader than any single program presently operating in the United States.

257 pages $7.00

ELEVEN INDICES

PREPARED BY Charles Kanno

This "aid in reviewing state and local mental health and hospital programs" is a successor to the long-established *Fifteen Indices*, published by the Joint Information Service since 1956. The new version eliminates some of the indices that are no longer applicable in view of changes in the mental health delivery system, adds new ones, and uses a different reporting form for others. It provides state-by-state data for expenditures for mental health programs, hospitalization rates, rehabilitated mental illness clients, percent of population living in community mental health center catchment areas, and so on. In addition, a separate profile is provided for each state, indicating its performance against the national averages.

Should old depressives be forgot?

Unable to concentrate, the geriatric depressive tends to take little interest in the affairs around him. His reactions are slow and delayed. He speaks very little. When he does, it's mostly to complain of his insomnia, fatigue, or constipation. Relatives often assume that many of the elderly are this way because they are old. In reality, they may be clinically depressed.

One way of relieving depression in the geriatric patient is with Tofranil.

It can help alleviate the somatic symptoms that often accompany depression.

A good response is generally observed in reactive depressions precipitated by a loss.

Because sedation may occur in some persons, especially the elderly, patients should be cautioned against driving a car or operating dangerous machinery.

Lower dosages are recommended for elderly patients and adolescents.

Please read the prescribing information for details of usage, precautions, warnings, contraindications, adverse experiences, and dosage recommendations. A summary of the prescribing information begins on the back of this page.

Tofranil® **Geigy**
imipramine hydrochloride USP

Tofranil® imipramine hydrochloride USP

Contraindications: The concomitant use of this agent and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 14 days after M.A.O.I. therapy has been discontinued should be allowed before this drug may be substituted. Initial dosage should be low, increases should be gradual, and the patient's progress should be carefully observed. The drug is also contraindicated (a) during the acute recovery period after myocardial infarction, (b) in patients with known hypersensitivity to the drug. Cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

- patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
- patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
- hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
- patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
- patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Usage in Children: Pending evaluation of results from clinical trials in children, the drug is not recommended for use in patients under twelve years of age.

Since the drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as operating an automobile or machinery, the patient should be cautioned accordingly.

Precautions: Because of the possibility of suicide in seriously depressed patients, careful supervision during the early phase of treatment is necessary and hospitalization may be required. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, imipramine may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g. paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential.

Adverse Reactions: *Carciovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with desipramine.

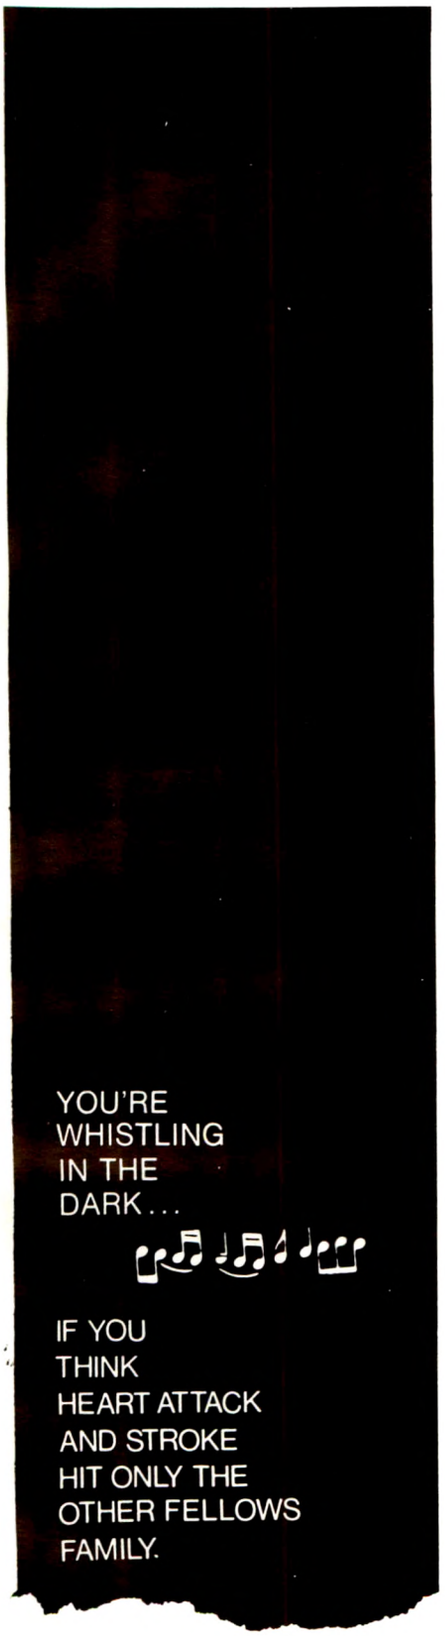
Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.



How Supplied: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST

AUTHORS: Louis S. Reed, Ph.D., Evelyn S. Myers, Patricia L. Scheidemandel

Those who hedge on granting the mentally ill adequate and equitable coverage under any national health insurance system have done so mainly on the ground that it would bankrupt the system. This book shows that this is not so. The most comprehensive study of the utilization and cost of care for mental disorders under health insurance ever undertaken, it gives facts and figures on more than 40 private health insurance plans or organizations, Medicare, other public programs in this country, and Canadian programs of hospital and medical service insurance. A wealth of data on inpatient care, in-hospital physicians' services, and ambulatory care is provided.

412 pages casebound $6.50
(2-6 copies, $6.00 ea.; 7-12 copies, $5.50 ea.; price for larger quantities supplied upon request)

EQUAL COVERAGE FOR THE MENTALLY ILL

The position statement of the American Psychiatric Association on the specifics of coverage of mental disorders under a National Health Insurance Program.

mirror, mirror on the wall, can this hospitalized schizophrenic relate to herself at all?

If the answer is "yes,"

then she can be helped to relate to others with the adjunctive use of

Trilafon®

brand of
perphenazine, NF

TRILAFON®
brand of perphenazine, NF
Tablets
REPETABS® Tablets
Syrup Concentrate Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON Injection should not be given to patients in coma or severely depressed states.

WARNINGS Usage in pregnancy: Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

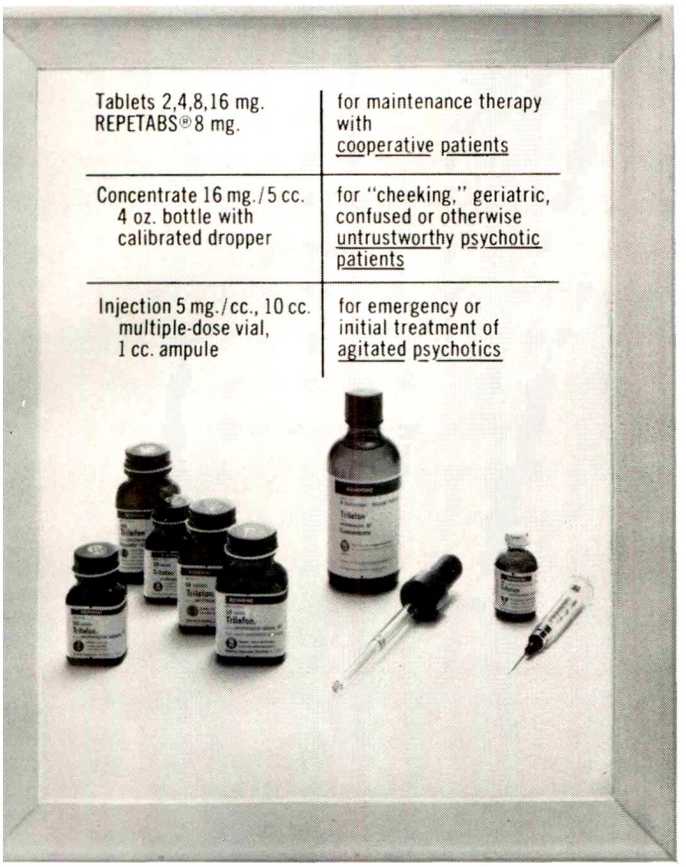
Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operat machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenaz should be under medical supervision, particularly if they are receiving h doses. Patients who have had any severe reaction to phenothiazines or to i pramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patie treated with perphenazine, the possibility that they might occur with TRILAF should be considered; blood dyscrasias (pancytopenia, thrombocytopenic purpu leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the vis fields; pigmentation of the retina, cornea, or lens; cerebral edema; polypha photophobia; hyperpyrexia.



If hypotension develops, levarterenol (norepinephrine) can be used, but epinephrine, because epinephrine's action is blocked and partly reversed by p phenazine. Severe, acute hypotension has occurred with the use of phenoth zines and is of particular concern in patients with mitral insufficiency pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic react to perphenazine; treatment with perphenazine should be stopped if this occu

The antiemetic effect of perphenazine can obscure signs of toxicity due overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefo contact of hands or clothing by those handling perphenazine solutions sho be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-syste depressant actions of opiates, antihistamines, barbiturates, and alcohol, I

Schering

A potent phenothiazine to help:

- maintain alertness level
- stabilize behavioral patterns
- relieve anxiety/agitation
- increase patient response to psychotherapy

Trilafon®

brand of

perphenazine, NF

a major tranquilizer for in-hospital control and take-home therapy

---

the usual dosage of these agents is required when they are administered
›mitantly with TRILAFON. Patients should be cautioned that their response
cohol may be increased while they are being treated with TRILAFON.
enothiazines also potentiate the effects of atropine, heat, and phosphorus
:ticides, and should be used with caution in persons exposed to these agents.

RSE REACTIONS *Extrapyramidal reactions:* dystonia including protru-
discoloration, aching and rounding of the tongue; tonic spasm of the mas-
›ry muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric
s, trismus, torticollis, retrocollis, muscle weakness, and aching and numb-
of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism;
rreflexia; and ataxia. The incidence and severity of these reactions usually
ase with increased dosage, but have occurred in some patients receiving
dosage. Reduction in dosage or treatment with an antispasmodic agent will
lly control extrapyramidal reactions. In some instances, however, these
ions may persist after discontinuation of treatment with perphenazine.
rsistent tardive dyskinesia: As with all antipsychotic agents, tardive dys-
sia may appear in some patients on long-term therapy or may appear after
therapy has been discontinued. The risk appears to be greater in elderly
nts on high-dose therapy, especially females. The symptoms are persistent
in some patients appear to be irreversible. The syndrome is characterized by
mical involuntary movements of the tongue, face, mouth or jaw (eg, pro-
on of tongue, puffing of cheeks, puckering of mouth, chewing movements).
etimes these may be accompanied by involuntary movements of extremities.
e is no known effective treatment for tardive dyskinesia; antiparkinsonism
ts usually do not alleviate the symptoms of this syndrome. It is suggested
all antipsychotic agents be discontinued if these symptoms appear. Should
necessary to reinstitute treatment, or increase the dosage of the agent, or
:h to a different antipsychotic agent, the syndrome may be masked. It has
reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON Injection have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON Injection is a rare occurrence.

For the psychiatrist

The documented properties of DALMANE® (flurazepam HCl) for sleep

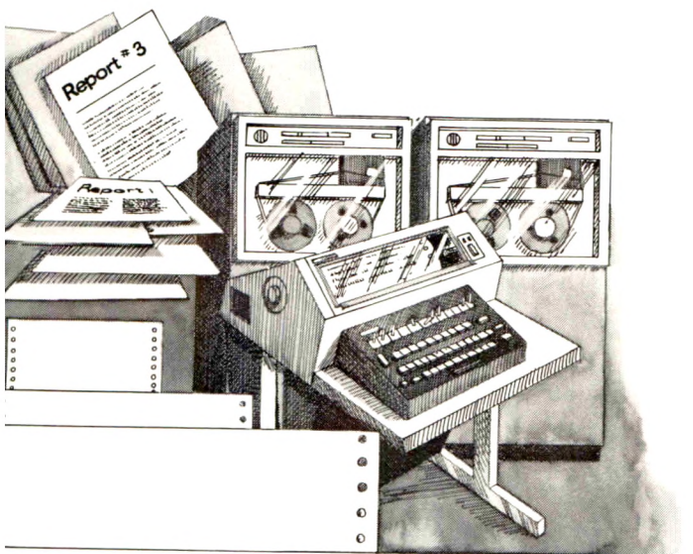
The properties of Dalmane have been carefully defined and thoroughly evaluated. Results of these investigations —many of which are cited here—have documented the effectiveness and relative safety of Dalmane when the etiology of insomnia indicates need for sleep medication.

The Roche Professional Services Department will, on request, supply you with detailed information about any of the clinical or pharmacologic aspects of Dalmane. To help, a computerized information resource called RETRIEVE will provide rapid answers to your specific questions. Details about this innovative information retrieval system are provided on the opposite page.

Prompt sleep induction, effective through the night[1-13]

Consistently effective night after night[2,3,5,6,8-13]

Relative safety[11,14,15*]



Usefulness in chronically anticoagulated patients[11]

Data about Dalmane (flurazepam HCl) on request

The references cited constitute only a part of the Dalmane bibliography. Additional data are available through the Roche Professional Services Department. Augmenting this service is RETRIEVE, a computer-operated data retrieval system which permits massive amounts of data to be searched, reviewed and selected rapidly and accurately. Coded into the computerized index are parameters that include patient age, sex, condition; product dose, side effect, frequency of administration; other medications or therapy; length, type and size of study and pharmacology.

For specific answers to any questions you might have about Dalmane, write or call: Roche Professional Services Department, Roche Laboratories, Nutley, N.J. 07110. Telephone: (201) 235-2355.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

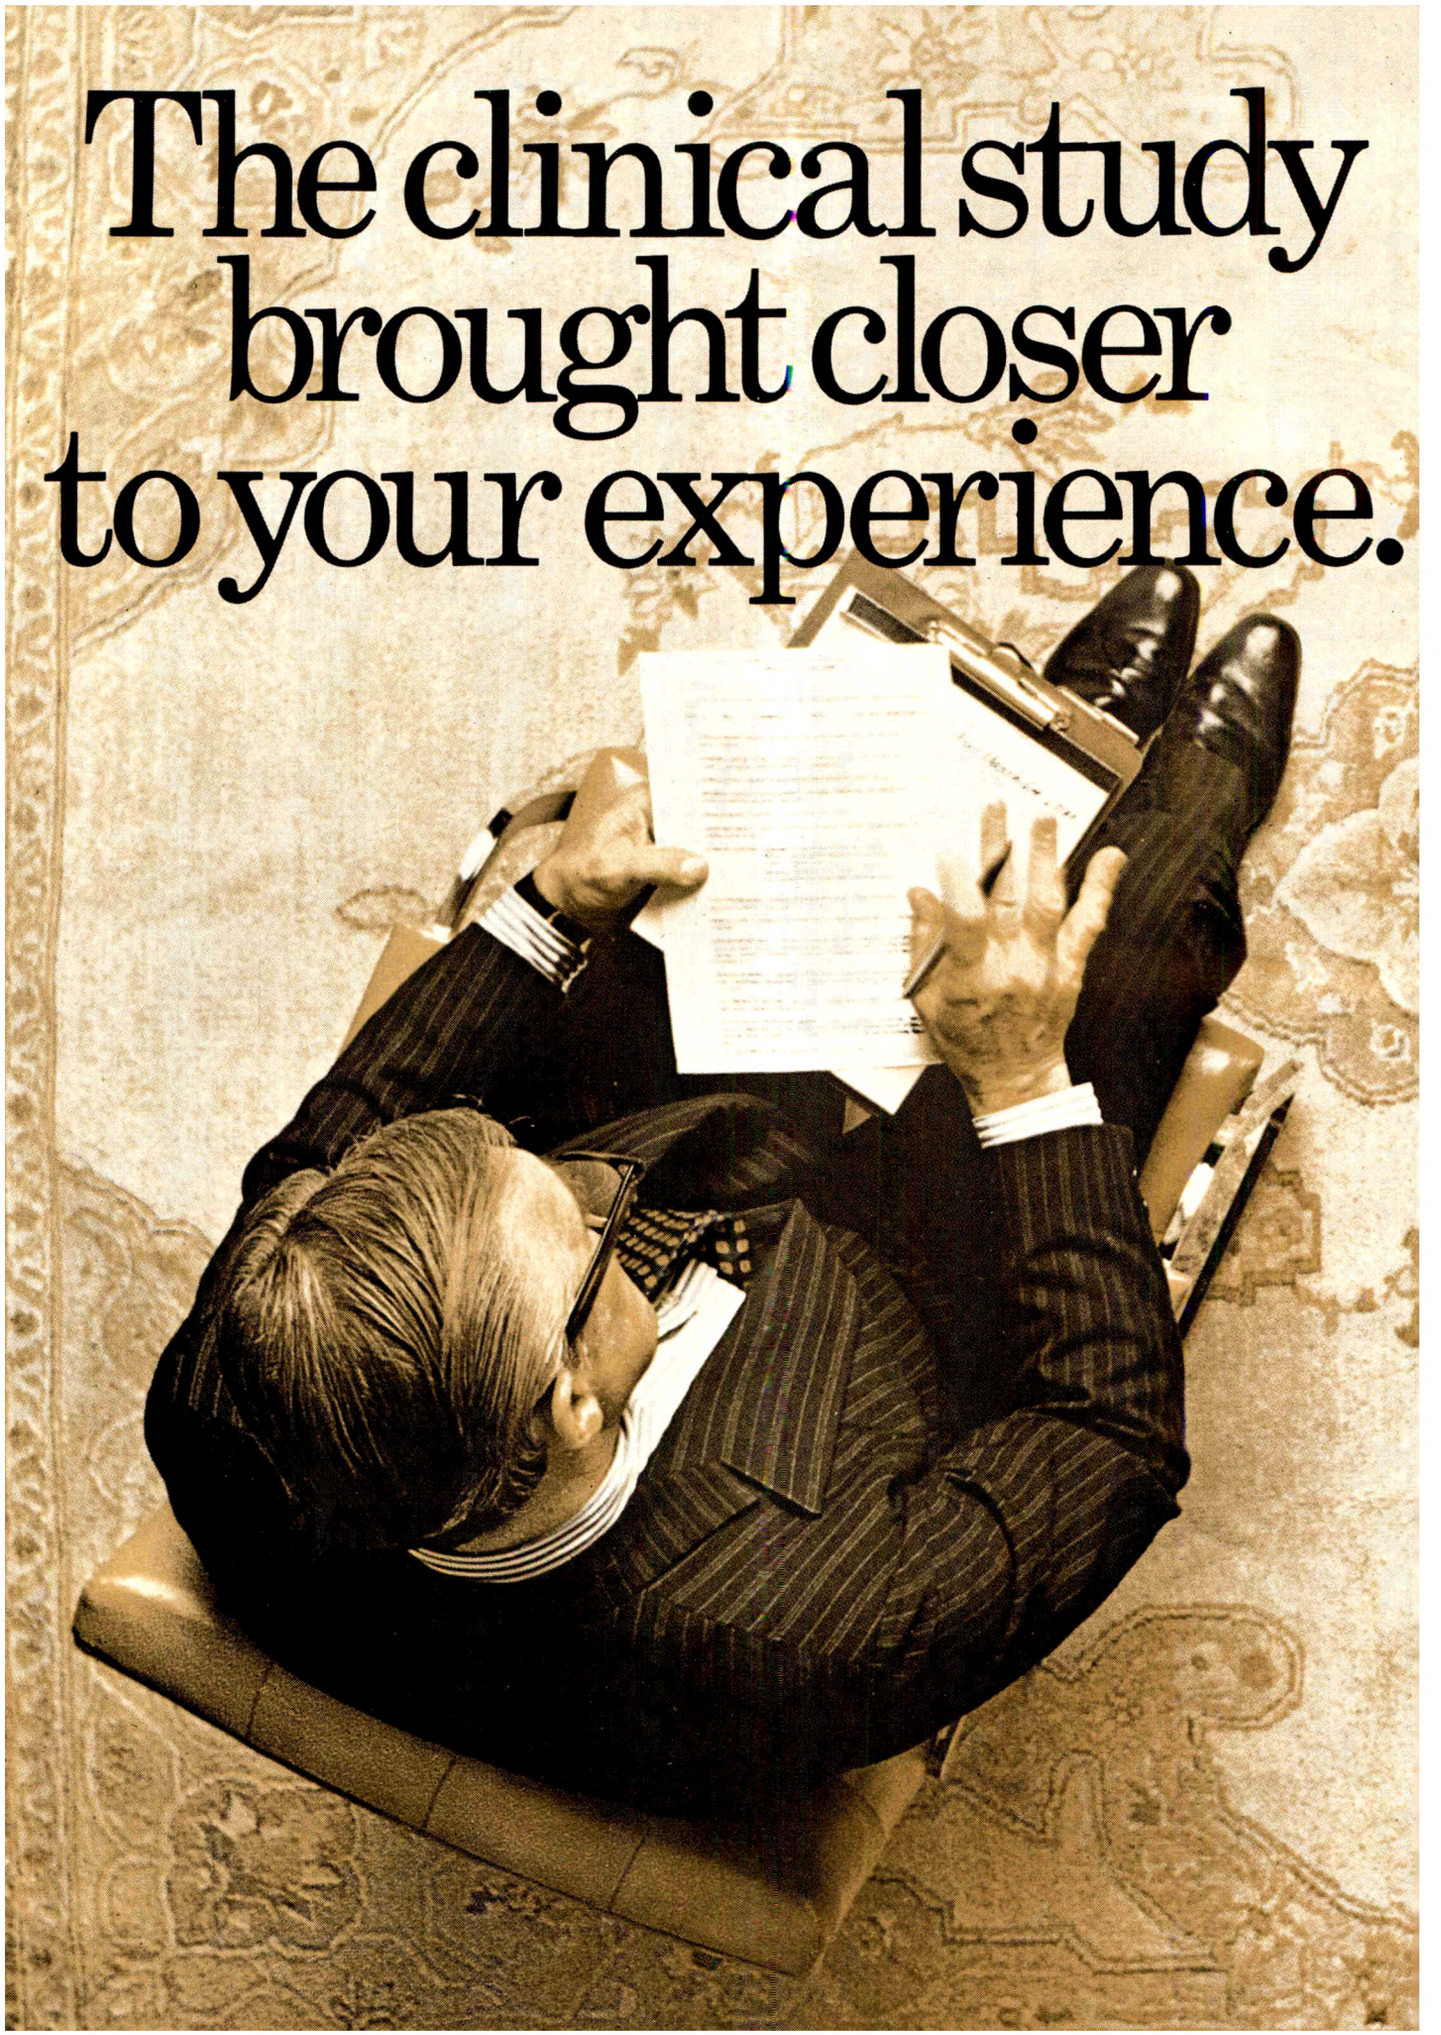
Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.



Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

DALMANE®
(flurazepam HCl)
When restful sleep is indicated

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

ROCHE LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

The clinical study brought closer to your experience.

Results of a "small scale" study of Valium®(diazepam) and placebo*

Six patients (3 men and 3 women) with prominent, persistent, high levels of anxiety (Taylor Manifest Anxiety Scale scores above 25) received Valium (diazepam) and placebo under double-blind conditions for six treatment periods of three days each, with a drug-free day between periods. Two dosage levels of Valium, 5 mg and 10 mg *t.i.d.*, and placebo were each administered for two periods.

Three methods of rating were employed in this study: physician's rating of symptoms, patient's self-rating, and patient's drug preference. Each patient's three main target symptoms were identified and rated by the physician initially and after each visit. Valium, at both dosage levels, gave higher physician ratings of symptom improvement than placebo, although the changes did not reach statistical significance. The six patients rated their own symptoms in order of severity at the initial interview and graded them daily as to the degree of improvement. In the patients' self-rating changes, both dosage levels of Valium gave higher ratings of improvement than placebo. Also, patients' preference recorded at the end of each week of the trial revealed that Valium (both dosage levels) was preferred over placebo to a significant degree.

"Small scale" drug trials use methods of observation and patient management similar to those you use in your practice.

The physician-investigator assessed Valium (diazepam) just as you might. He treated a small number of persistently anxious patients. He saw them frequently, supporting them, and rated changes in symptoms and had his patients do likewise. He noted the patient's preference for one medication over another. He found that Valium was effective, just as others have in larger, conventional studies, and just as you can find in your practice.

If you have not prescribed Valium, select a few overly anxious, psychoneurotic patients with or without associated or secondary depressive symptoms, and give Valium a trial of your own. You'll find it can significantly reduce anxiety and thus may facilitate psychotherapy and make patients more comfortable. Caution patients on Valium against driving or operating machinery. Side effects most commonly reported have been drowsiness, fatigue and ataxia.

*McLeod, W.R.; Mowbray, R. M., and Davies, B.: Scientific exhibit presented at the Interstate Postgraduate Medical Association of North America, Nov. 15-18, 1971, New Orleans, La.

Valium®(diazepam)
2-mg, 5-mg and 10-mg tablets

Please see the following page for a summary of product information.

Valium® (diazepam)
For overanxious, tense psychoneurotics with or without associated or secondary depressive symptoms

Effectiveness—Valium (diazepam) can relieve tension-induced symptoms—psychic and somatic—in patients thus overreacting to situational stresses as well as in patients with psychoneuroses.

Excellent tolerance—Valium (diazepam) tablets generally do not significantly affect respiration, pulse or heart rate on recommended dosage. The most frequent side effects are drowsiness, ataxia and fatigue. Caution patient against driving or operating dangerous machinery while on Valium.

Titratable dosage—With Valium, small adjustments in dosage can significantly alter the clinical response. This titratability enables you to tailor your prescriptions for maximum efficiency. There are three tablet strengths from which to choose: 2 mg, 5 mg and 10 mg.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

H lp improv your d pr ss d patients' ability to cope.

In Brief:
Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.
Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.
Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.
Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.
Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Close supervision and careful adjustment of dosage are required when this drug is given along with anticholinergic or sympathomimetic drugs. While taking this drug response to alcoholic beverages may be exaggerated. There is limited clinical experience in the concurrent administration of ECT and antidepressant drugs; thus, one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.
Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50, 250 and 1000 tablets.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

The documented properties of DALMANE® (flurazepam HCl) for sleep

The properties of Dalmane have been carefully defined and thoroughly evaluated. Results of these investigations —many of which are cited here—have documented the effectiveness and relative safety of Dalmane when the etiology of insomnia indicates need for sleep medication.

The Roche Professional Services Department will, on request, supply you with detailed information about any of the clinical or pharmacologic aspects of Dalmane. To help, a computerized information resource called RETRIEVE will provide rapid answers to your specific questions. Details about this innovative information retrieval system are provided on the opposite page.

Prompt sleep induction, effective through the night[1-13]

Consistently effective night after night[2,3,5,6,8-13]

Relative safety[11,14,15*]

Usefulness in chronically anticoagulated patients[11]

DALMANE®
(flurazepam HCl)
IS IN A CLASS BY ITSELF.
Not a narcotic, barbiturate or methaqualone, Dalmane is the only available benzodiazepine specifically indicated for insomnia.

*Generally, when adverse effects were reported clinically with Dalmane (flurazepam HCl), they were mild and infrequent. Dizziness, drowsiness, lightheadedness and the like were the side effects noted most often, particularly in the elderly or debilitated. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

Little "hang-over" effect on awakening[11,14]

Data about Dalmane (flurazepam HCl) on request

The references cited constitute only a part of the Dalmane bibliography. Additional data are available through the Roche Professional Services Department. Augmenting this service is RETRIEVE, a computer-operated data retrieval system which permits massive amounts of data to be searched, reviewed and selected rapidly and accurately. Coded into the computerized index are parameters that include patient age, sex, condition; product dose, side effect, frequency of administration; other medications or therapy; length, type and size of study and pharmacology.

For specific answers to any questions you might have about Dalmane, write or call: Roche Professional Services Department, Roche Laboratories, Nutley, N.J. 07110. Telephone: (201) 235-2355.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

DALMANE®
(flurazepam HCl)
When restful sleep is indicated

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

THE FACILITY FOR CONTINUING EDUCATION
McLEAN HOSPITAL

(A training facility in psychiatry
of the Harvard Medical School)

ANNOUNCES A NATIONAL CONFERENCE ON

crisis intervention

IN THE HOME, SCHOOL AND COMMUNITY

BOSTON, MASSACHUSETTS MAY 16-20, 1973

Directed by STANLEY ELDRED, M.D., Associate Professor of Psychiatry, Harvard Medical School

For teachers, counselors, school administrators, social workers, clergymen, recreation workers, hot line operators, drug abuse workers, physicians, law enforcement agents, psychologists, psychiatrists, and others interested in an intensive, three-day training session and interdisciplinary dialogue on effective approaches to intervening with children, adolescents, adults and families in crisis.

Tuition: $150. Strictly limited to 200 participants. For further information and applications: Cambridge Educational Associates, 1430 Massachusetts Avenue, Harvard Square, Cambridge, Massachusetts 02138, or phone 617/492-6662.

25th Institute
on
Hospital & Community Psychiatry

September 17–20, 1973
Americana Hotel, Miami Beach, Florida

THEME: "A Quarter of a Century: Where are We Now?"

Faculty and participants will critically examine and discuss the past, present and future of delivery of mental health systems in three categories:

Economics of Mental Health Care

Effects of Legislation and Judicial Decisions on Delivery and Care

Biological, Psychological, and Sociological Perspectives for Care and Delivery Systems.

For detailed program information, registration form and application for Technical and Scientific exhibits contact:

on

"Schizophrenia"

mirror, mirror on the wall, can this hospitalized schizophrenic relate to herself at all?

If the answer is "yes,"

then she can be helped to relate to others with the adjunctive use of

Trilafon®

brand of
perphenazine, NF

TRILAFON®
brand of perphenazine, NF
Tablets
REPETABS® Tablets
Syrup Concentrate Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON Injection should not be given to patients in coma or severely depressed states.

WARNINGS Usage in pregnancy: Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operat machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenaz should be under medical supervision, particularly if they are receiving h doses. Patients who have had any severe reaction to phenothiazines or to i pramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patie treated with perphenazine, the possibility that they might occur with TRILA should be considered; blood dyscrasias (pancytopenia, thrombocytopenic purp leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the vis fields; pigmentation of the retina, cornea, or lens; cerebral edema; polypha photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but epinephrine, because epinephrine's action is blocked and partly reversed by p phenazine. Severe, acute hypotension has occurred with the use of phenoth zines and is of particular concern in patients with mitral insufficiency pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic react to perphenazine; treatment with perphenazine should be stopped if this occu

The antiemetic effect of perphenazine can obscure signs of toxicity due overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefo contact of hands or clothing by those handling perphenazine solutions sho be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-syste depressant actions of opiates, antihistamines, barbiturates, and alcohol, I

Schering

Tablets 2,4,8,16 mg. REPETABS® 8 mg.	for maintenance therapy with cooperative patients
Concentrate 16 mg./5 cc. 4 oz. bottle with calibrated dropper	for "cheeking," geriatric, confused or otherwise untrustworthy psychotic patients
Injection 5 mg./cc., 10 cc. multiple-dose vial, 1 cc. ampule	for emergency or initial treatment of agitated psychotics

A potent phenothiazine to help:

- maintain alertness level
- stabilize behavioral patterns
- relieve anxiety/agitation
- increase patient response to psychotherapy

Trilafon®

brand of

perphenazine, NF

a major tranquilizer for in-hospital control and take-home therapy

---

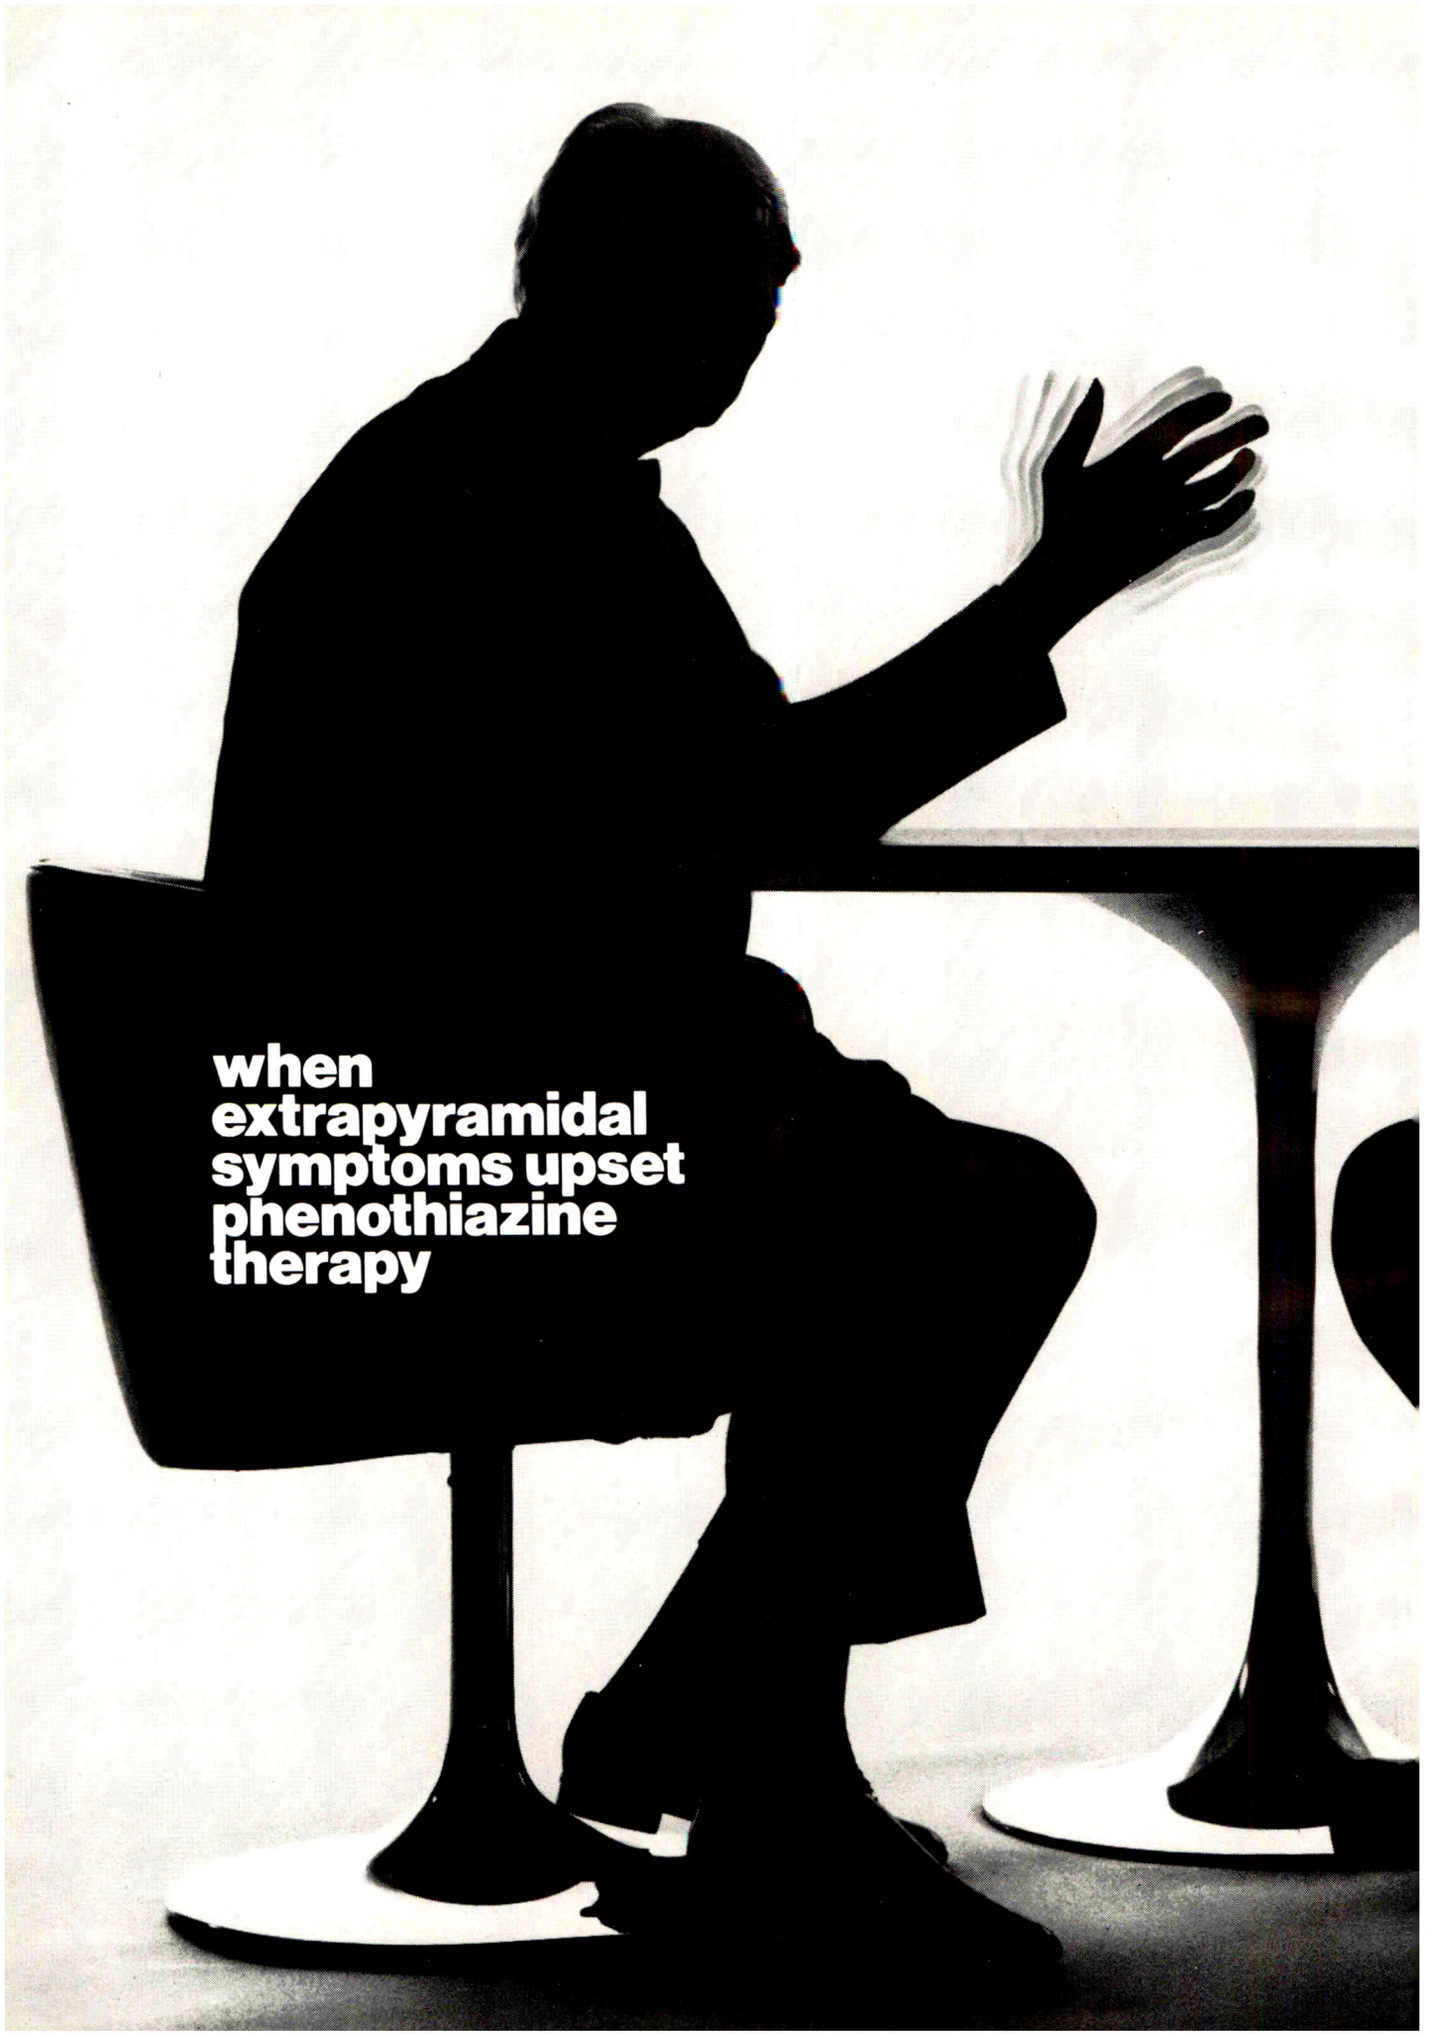
he usual dosage of these agents is required when they are administered nitantly with TRILAFON. Patients should be cautioned that their response ohol may be increased while they are being treated with TRILAFON.
nothiazines also potentiate the effects of atropine, heat, and phosphorus icides, and should be used with caution in persons exposed to these agents.

SE REACTIONS *Extrapyramidal reactions:* dystonia including protru- liscoloration, aching and rounding of the tongue; tonic spasm of the mas- ry muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric trismus, torticollis, retrocollis, muscle weakness, and aching and numb- of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; eflexia; and ataxia. The incidence and severity of these reactions usually se with increased dosage, but have occurred in some patients receiving sage. Reduction in dosage or treatment with an antispasmodic agent will control extrapyramidal reactions. In some instances, however, these ns may persist after discontinuation of treatment with perphenazine.
sistent tardive dyskinesia: As with all antipsychotic agents, tardive dys- a may appear in some patients on long-term therapy or may appear after therapy has been discontinued. The risk appears to be greater in elderly ts on high-dose therapy, especially females. The symptoms are persistent some patients appear to be irreversible. The syndrome is characterized by nical involuntary movements of the tongue, face, mouth or jaw (eg, pro- n of tongue, puffing of cheeks, puckering of mouth, chewing movements). imes these may be accompanied by involuntary movements of extremities. is no known effective treatment for tardive dyskinesia; antiparkinsonism usually do not alleviate the symptoms of this syndrome. It is suggested ll antipsychotic agents be discontinued if these symptoms appear. Should necessary to reinstitute treatment, or increase the dosage of the agent, or to a different antipsychotic agent, the syndrome may be masked. It has reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.



Side effects with intramuscular TRILAFON Injection have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON Injection is a rare occurrence.

SWW-270

when
extrapyramidal
symptoms upset
phenothiazine
therapy

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/cc

COGENTIN®
(BENZTROPINE MESYLATE | MSD)

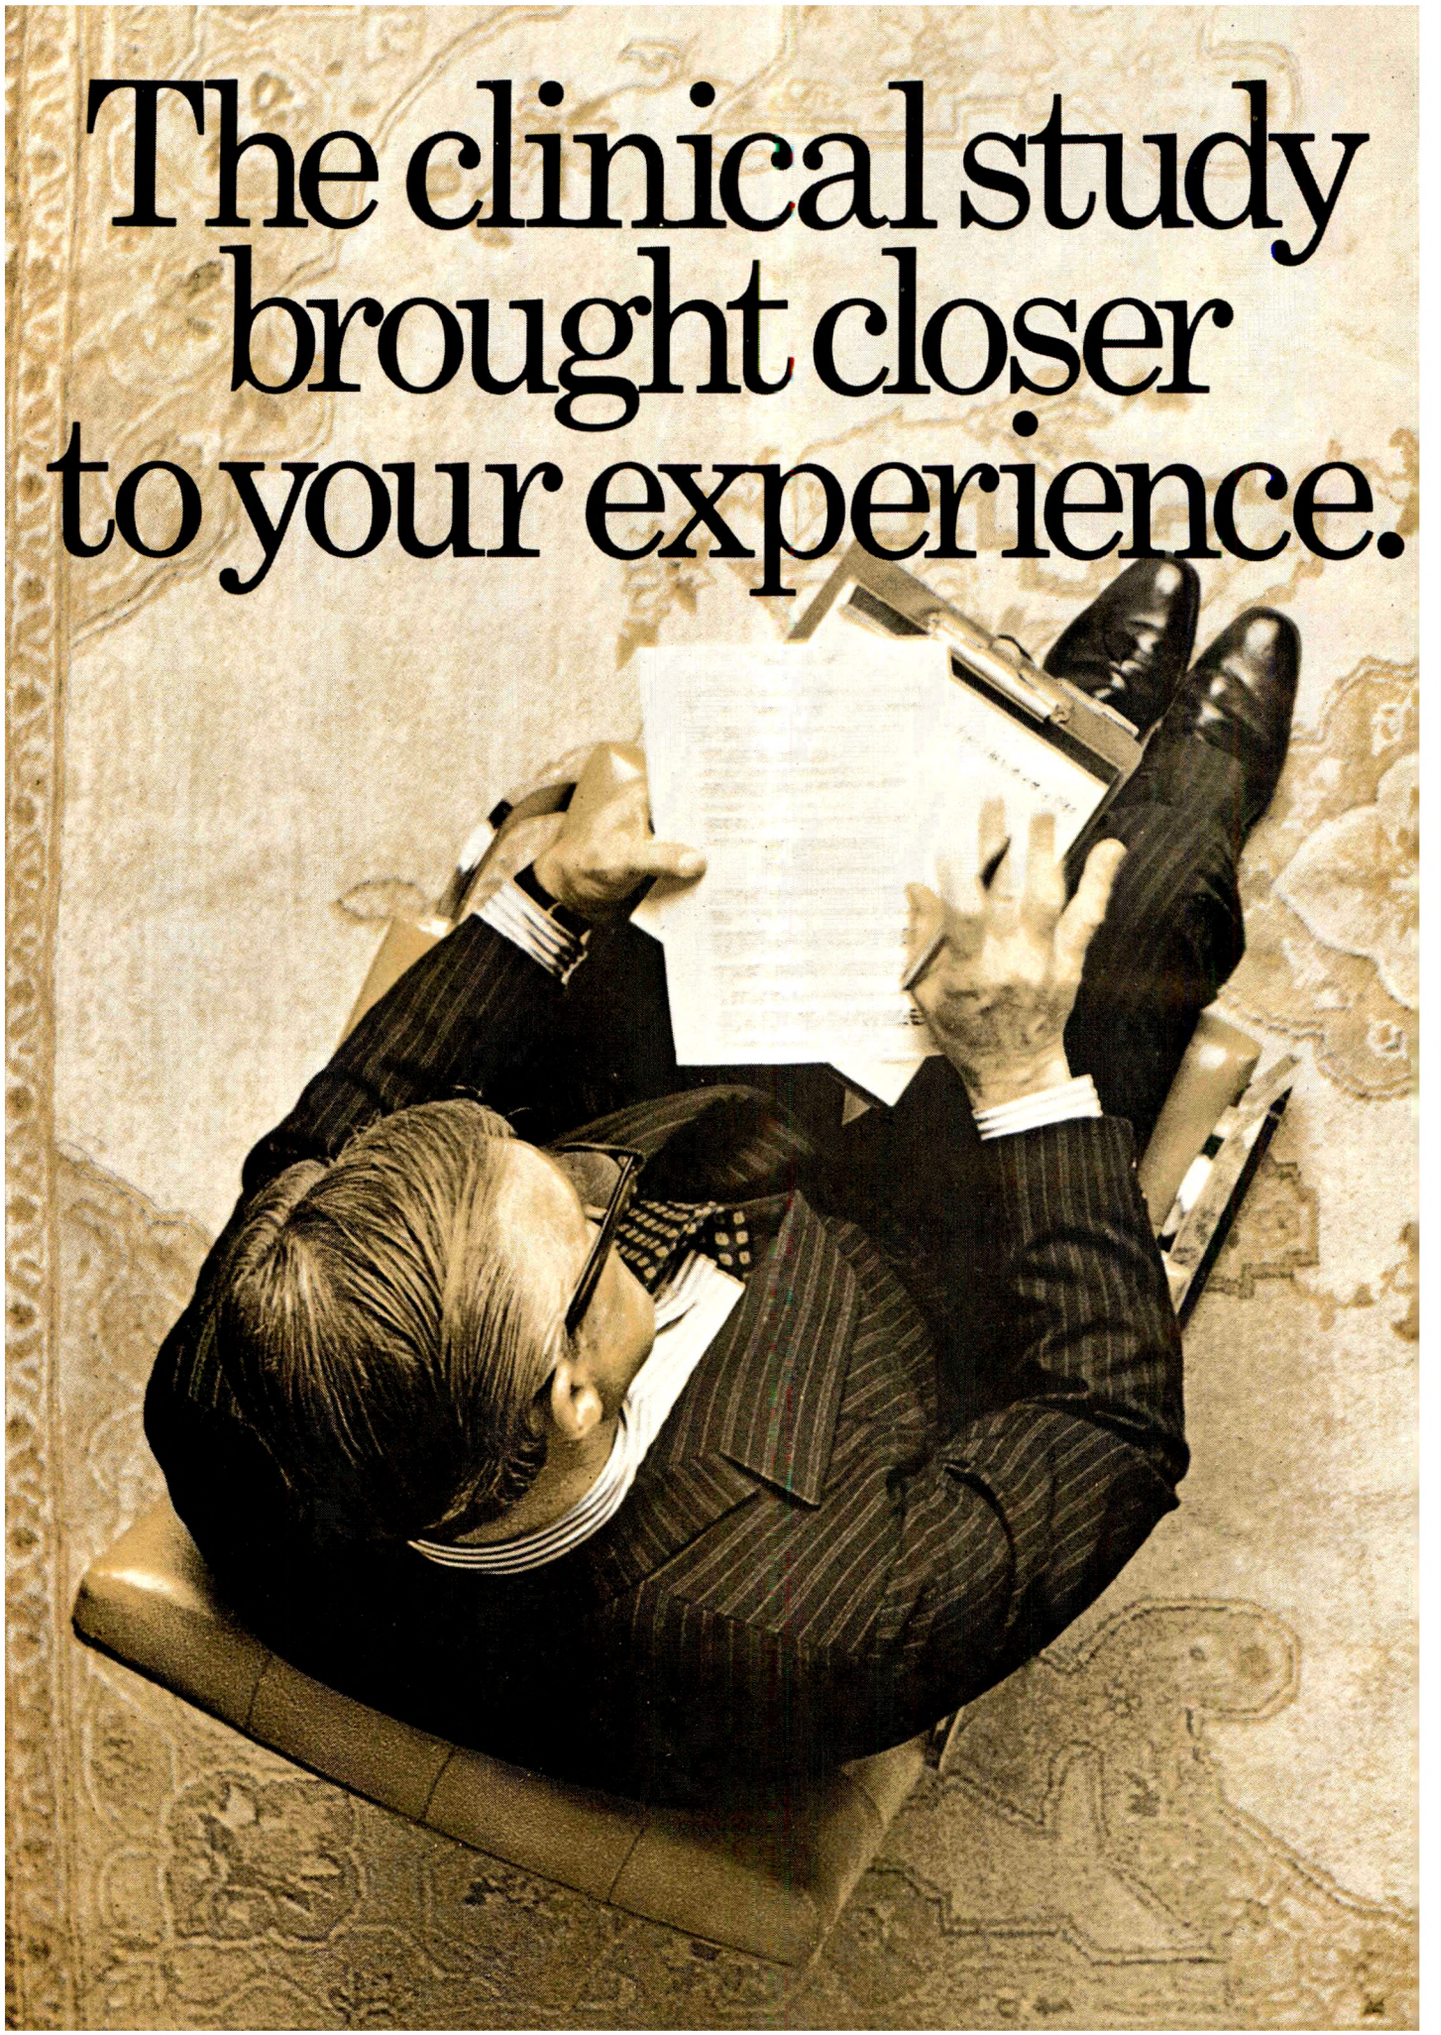
helps keep productive therapy from becoming counterproductive

- Helps relieve rigidity and tremor
- Provides long duration of action
- Frequently permits continuation of the phenothiazine without change of dosage

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.
Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.
May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.
Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.



Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per cc, in 2-cc ampuls.

For more detailed information, consult your MSD representative or see the Direction Circular. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

MSD MERCK SHARP & DOHME

The clinical study brought closer to your experience.

Results of a "small scale" study of Valium®(diazepam) and placebo*

Six patients (3 men and 3 women) with prominent, persistent, high levels of anxiety (Taylor Manifest Anxiety Scale scores above 25) received Valium (diazepam) and placebo under double-blind conditions for six treatment periods of three days each, with a drug-free day between periods. Two dosage levels of Valium, 5 mg and 10 mg *t.i.d.*, and placebo were each administered for two periods.

Three methods of rating were employed in this study: physician's rating of symptoms, patient's self-rating, and patient's drug preference. Each patient's three main target symptoms were identified and rated by the physician initially and after each visit. Valium, at both dosage levels, gave higher physician ratings of symptom improvement than placebo, although the changes did not reach statistical significance. The six patients rated their own symptoms in order of severity at the initial interview and graded them daily as to the degree of improvement. In the patients' self-rating changes, both dosage levels of Valium gave higher ratings of improvement than placebo. Also, patients' preference recorded at the end of each week of the trial revealed that Valium (both dosage levels) was preferred over placebo to a significant degree.

"Small scale" drug trials use methods of observation and patient management similar to those you use in your practice.

The physician-investigator assessed Valium (diazepam) just as you might. He treated a small number of persistently anxious patients. He saw them frequently, supporting them, and rated changes in symptoms and had his patients do likewise. He noted the patient's preference for one medication over another. He found that Valium was effective, just as others have in larger, conventional studies, and just as you can find in your practice.

If you have not prescribed Valium, select a few overly anxious, psychoneurotic patients with or without associated or secondary depressive symptoms, and give Valium a trial of your own. You'll find it can significantly reduce anxiety and thus may facilitate psychotherapy and make patients more comfortable. Caution patients on Valium against driving or operating machinery. Side effects most commonly reported have been drowsiness, fatigue and ataxia.

*McLeod, W. R.; Mowbray, R. M., and Davies, B.: Scientific exhibit presented at the Interstate Postgraduate Medical Association of North America, Nov. 15-18, 1971, New Orleans, La.

Valium®(diazepam)
2-mg, 5-mg and 10-mg tablets

Please see the following page for a summary of product information.

Valium® (diazepam)
For overanxious, tense psychoneurotics with or without associated or secondary depressive symptoms

Effectiveness—Valium (diazepam) can relieve tension-induced symptoms—psychic and somatic—in patients thus overreacting to situational stresses as well as in patients with psychoneuroses.

Excellent tolerance—Valium (diazepam) tablets generally do not significantly affect respiration, pulse or heart rate on recommended dosage. The most frequent side effects are drowsiness, ataxia and fatigue. Caution patient against driving or operating dangerous machinery while on Valium.

Titratable dosage—With Valium, small adjustments in dosage can significantly alter the clinical response. This titratability enables you to tailor your prescriptions for maximum efficiency. There are three tablet strengths from which to choose: 2 mg, 5 mg and 10 mg.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

ROCHE

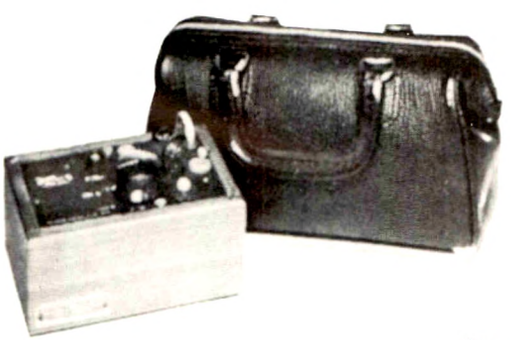
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

Visit Booth No. 33 at the Annual Meeting

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate)
helps the patient respond in mild depression*

Ritalin® hydrochloride ©
methylphenidate hydrochloride)
TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established. Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

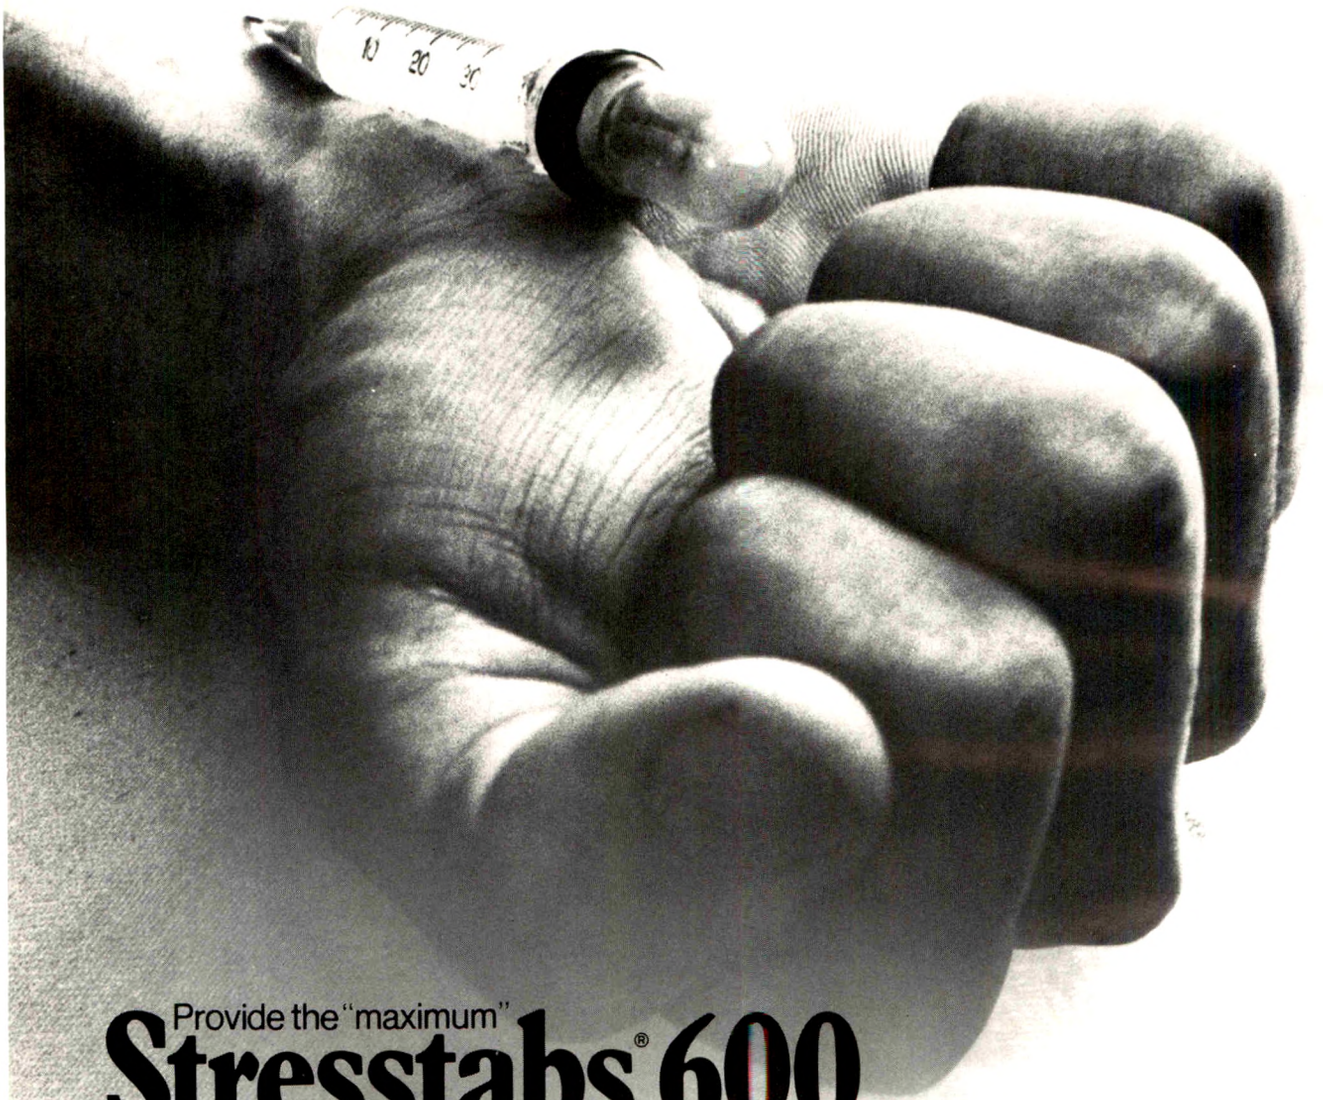
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening.
Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.



HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.
Consult complete product literature before prescribing.

Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg., 2 mg., 5 mg., 10 mg. Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

to help control psychotic behavior

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg.
Concentrate: 5 mg./cc.
Intramuscular: 2 mg./cc.

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg.
(thiothixene hydrochloride)
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the midlateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration because safe conditions for its use have not been established.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Usage in children under 12 years of age is not recommended.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of behavior is desirable, the intramuscular form of Navane (thiothixene hydrochloride) may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg. of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg./day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg. three times daily. If indicated, a subsequent increase to 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. daily. If indicated, an increase to 60 mg./day total daily dose is often effective. Exceeding a total daily dose of 60 mg. rarely increases the beneficial response.

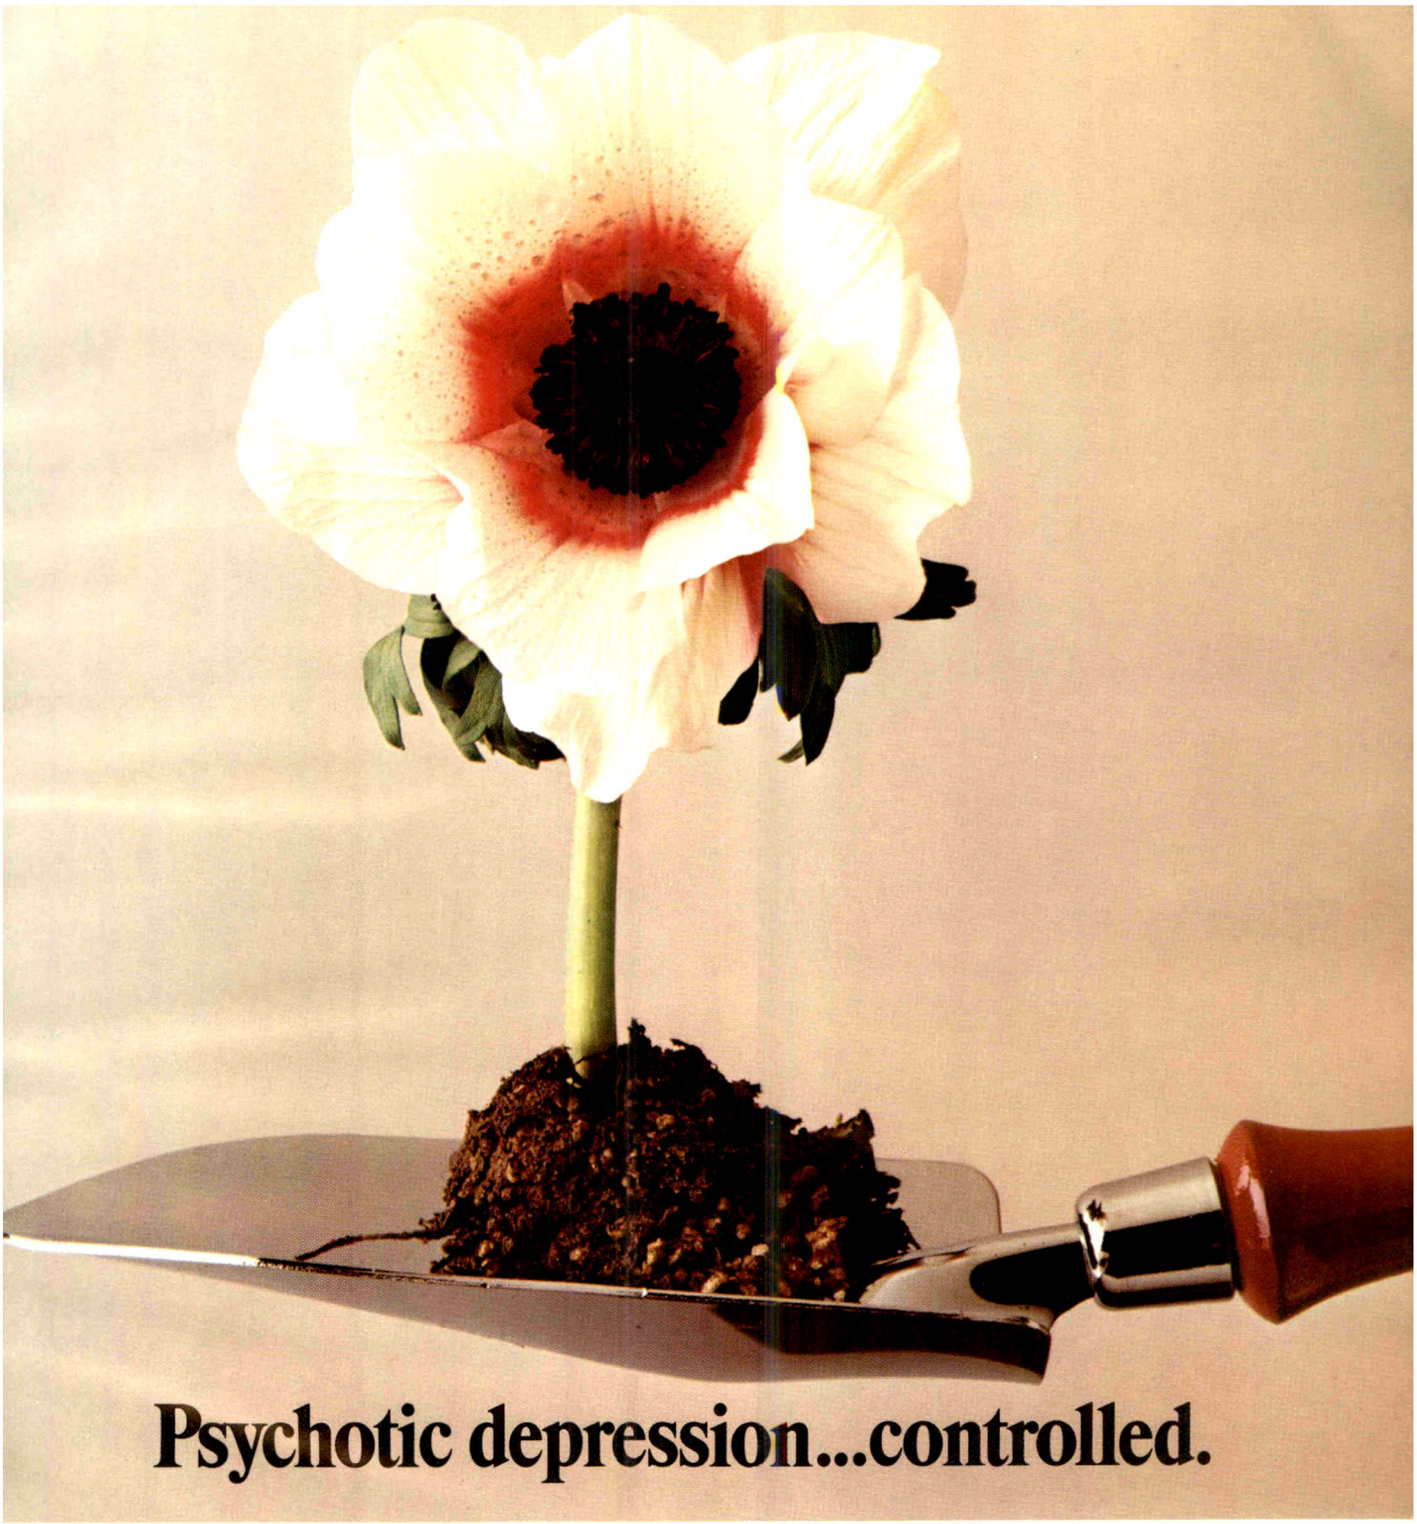
Some patients have been successfully maintained on once-a-day Navane (thiothixene) therapy.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.



There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg., 2 mg., 5 mg., and 10 mg. in bottles of 100 and 1,000.

Navane (thiothixene hydrochloride) Concentrate is available in 120 cc. (4 oz.) bottles with an accompanying dropper calibrated at 2 mg., 4 mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each cc. contains thiothixene hydrochloride equivalent to 5 mg. of thiothixene. Contains alcohol, U.S.P. 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular Solution is available in a 2 cc. amber glass vial in packages of 10. Each cc. contains thiothixene hydrochloride equivalent to 2 mg. of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Psychotic depression...controlled.

Navane (thiothixene) helps reduce the intensity and frequency of depression as manifested in psychotic disorders. Mental and motor retardation may be replaced by an increasing interest in self and environment and a return to productive activity. Severe mood disorders may be relieved to encourage cooperation with therapy and daily routine. Navane...an effective anti-psychotic.

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

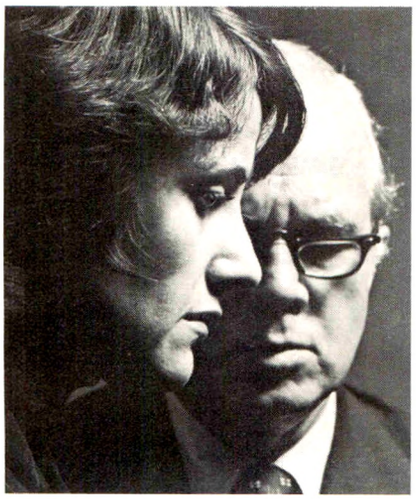
MERCK SHARP & DOHME



For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety
or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice
when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; pregnancy; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction. Not recommended in children.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, narrow-angle glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage.
The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant drug. Patients with paranoid symptomatology may have an exaggeration of such symptoms.
The tranquilizing effect of TRIAVIL has seemed to reduce the likelihood of this effect.
Supervise closely and carefully adjust dosage when given with anticholinergic agents and sympathomimetic drugs.
The drug may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards of therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible.
Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonos, oculogyric crises, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reaction); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galac-

orrhea, disturbances of menstrual cycle); altered cerebrospinal luid proteins; paradoxical excitement; ECG abnormalities quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dryness of he mouth, headache, nausea, vomiting, constipation, obstipaion, urinary frequency, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

For more detailed information, consult your MSD Representative or see full Prescribing Information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance — vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.

Anxiety Amelioration — in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa. 19101

Please see important information on page after next.

UNIVERSITY COLLEGE
LIBRARY
C. U.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

Serax®
(oxazepam)

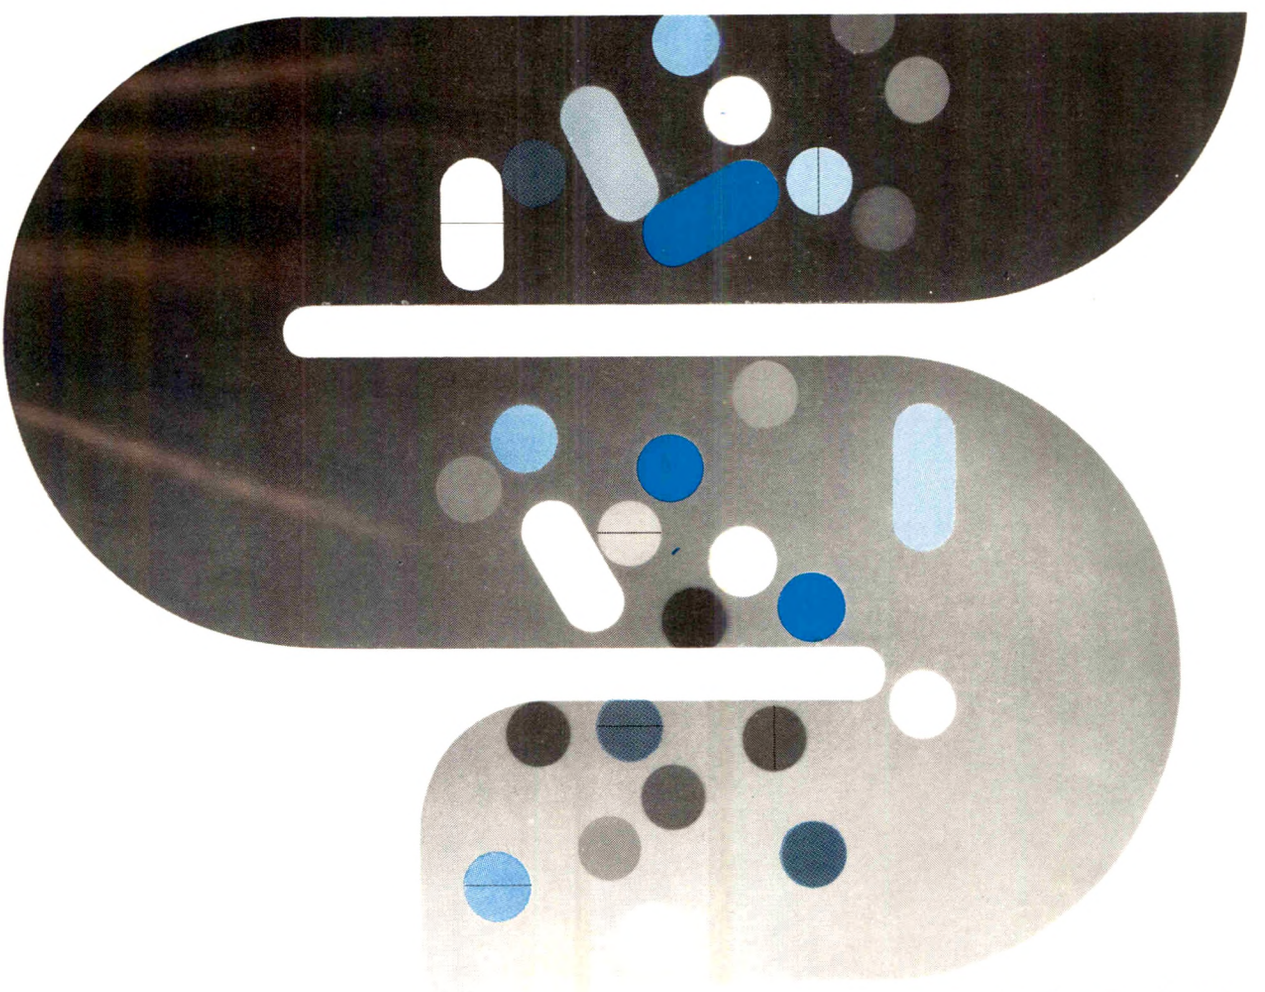
Wyeth Laboratories
Philadelphia, Pa. 19101

Drug-Induced Constipation

Many of the widely prescribed drug categories—antacids, analgesics, barbiturates, tranquilizers, diuretics, hematinics, antihistamines, anticholinergics, antispasmodics, narcotics, muscle relaxants, antihypertensives, antidepressants—may interfere with the regular bowel action.

The value of SENOKOT Tablets/Granules has been clearly demonstrated in drug-induced or drug-aggravated constipation. In 5 studies* SENOKOT therapy was effective in 98.5% of 613 cases.

When an essential drug you prescribe induces or aggravates constipation, Rx or recommend a SENOKOT laxative product. Compatible with antacids, clinically tested, shown not to interfere with the action of numerous drugs, it is the *natural* choice to keep things moving gently, comfortably, effectively.



Supplied: SENOKOT Tablets (small, easy-to-swallow)—Bottles of 50 and 100. SENOKOT Granules (delicious, cocoa-flavored)—4, 8 and 16 ounce (1 lb.) canisters.

*References on request.

Counteract with Senokot

(standardized senna concentrate)

when anxiety and depression travel together through the pathways of the neurotic mind.*...

Mellaril®
(thioridazine)

TABLETS, 25 mg. and 50 mg. thioridazine HCl, U.S.P.
Usual starting dosage: 25 mg. t.i.d.

*Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified this indication as "probably" effective.
Final classification of the less-than-effective indications requires further investigation.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.
The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

SANDOZ

THE AMERICAN JOURNAL OF PSYCHIATRY

The Future of Psychiatric Education

BY LOUIS JOLYON WEST, M.D.

The psychiatrist of tomorrow, while retaining his hard-won expertise in psychodynamics and psychotherapy, will be considerably more of a neurobiologist, endocrinologist, behavioral scientist, even mathematician, than is common today. He will be expected to integrate advances in research on both brain and behavior, and to apply the amalgam in a truly biosocial approach to the field of mental health and the practice of medicine. Therefore the psychiatrist's education must provide him with a great variety of knowledge without sacrificing depth, scholarship, or humanity. Four years of college, four of medical school (with the emphasis on breadth and enrichment rather than on early specialization and shortcuts), and four of rigorous postdoctoral education will not be considered irrelevant or excessive. Furthermore, psychiatry and the behavioral sciences will become increasingly important in the education of all physicians and other health professionals. Thus liaison teaching will be a major responsibility of psychiatric educators in the future.

THE FUTURE OF PSYCHIATRIC EDUCATION is inextricably linked with the future of medical education in general. Advances in psychiatry will derive naturally from new knowledge produced by basic and applied research in the biomedical and behavioral sciences and from ongoing clinical investigation in various disciplines, including our own. Progress will also be a benefit of developments in educational technology: the use of film, audio- and videotapes and cassettes, programmed instruction, modular student laboratories, library carrels with individual computer terminals and viewing screens, and so forth.

At the same time the content of psychiatric education will necessarily reflect the evolution of psychiatry itself. Physicians must become increasingly well equipped to utilize a knowledge of psychiatry in the practice of medicine, whether or not they become psychiatrists, and specialists in psychiatry must be trained in light of the latest advances in the field. Therefore I have chosen in this discussion to emphasize my view of psychiatry to come, for which the psychiatric education of the future should be the preparation.

Coleridge said, "In today already walks tomorrow." What harbingers of future psychiatry can be seen in the present? Our specialty today contains much that seems new to those whose medical education—like mine—began more than a quarter of a century ago. Newness, of course, is not synonymous with value. As the philosopher Herbert Feigl once remarked about the teachings of Count Alfred Korzybski, "All that is good in general semantics is not necessarily new; and all that is new in it is not necessarily good!"

I would make the same declaration about certain current trends in medical education (e.g., shortening the basic course of study, eliminating the internship, fostering earlier commitments by students to specialties). There are even those who would say it about recent developments in psychiatry as a whole. The community mental health movement, for instance, has not been without its critics, from Ralph Nader to Thomas Szasz. Even supporters, like myself, of the general effort to make our field more relevant to major social issues and community concerns have been bemused by some of the recent setbacks for psychiatry. These setbacks have followed in the wake of major government emphasis upon and investment in mental health service delivery systems emphasizing comprehensive community mental health centers, seemingly (if not truly) at the expense of fundamental psychiatric education and research.

The past and the present of psychiatry have much to teach us. We must learn from our mistakes. As an example, the danger of being oversold, either by our own enthusiasm or by that of our friends, should now be clear to all of us. We must be sure in the future to teach our students not only the value of psychiatry and its genuine possibilities, but also its limitations and the risks attending excessive expectations by practitioners and public alike.

Certainly we would be wise to learn from the history of

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. West is Professor and Chairman, Department of Psychiatry, School of Medicine, University of California at Los Angeles, Calif. 90024.

psychiatry. But positive projections for the future must stem from our vision of that future. As Burke said, "You can never plan the future by the past." Looking ahead, I believe that one of the most impressive requirements for psychiatric education will be its responsiveness to the great surge of science, which is producing new information at an awesome rate.

NEW KINDS OF KNOWLEDGE

The information explosion in this decade will reach fantastic proportions. Biochemistry, biophysics, genetics, membrane physiology, molecular biology, and developmental biology will progress so fast and so far that we shall barely be able to grasp the significance of their advances, much less claim them for psychiatry. Nevertheless, psychiatry's responsibility will be to comprehend scientific progress in the biological sciences, to integrate it meaningfully with the behavioral sciences (where there is also an information explosion going on), and creatively to seek applications of the resulting compound that will be relevant to mental health and the practice of medicine.

Therefore the psychiatrist of the future, to fulfill his destiny as a creative integrator in applied psychobiology, will be required to master the tools of synthesis: an exceptionally broad scientific vocabulary; familiarity with communication theory, information theory, general systems theory, and the like; and a working knowledge of the most useful conceptual models that the state of science will have generated by that time.

Mathematical Models

For example, I predict the increasing use of mathematical models in psychiatric research. Physicists have had to make fundamental distinctions among scalar, vector, and high-order tensor quantities. Psychiatrists, psychologists, and even sociologists eventually will be required to do the same. We shall of course continue to construct nonnumerical models. However, the mathematical variety is more powerful in its descriptive and predictive ability. Furthermore, the quantitative analysis of psychological and social events in relation to biological and physical ones would be greatly facilitated if mathematical models were employed.

The creation of such models will be based not only on advances in science but on a much sounder understanding of mathematical logic. Soon, central nervous system functions will be studied by the employment of models with special topological properties, as well as by statistical models comparable to those used today by physicists in statistical mechanics and quantum statistics.

In areas such as learning, motivation, and personality (including diagnosis and psychotherapy) we must continue to strive to develop effective models of the universal type; a truly unified behavioral science requires them. Progress along these lines could permit the redevelopment of a field-theoretical approach to behavior, allowing a closer linkage between biophysical and behavioral events. In this development many of the significant and neglected contributions of Gestalt and Lewinian psychology might finally find their proper, honorable place.

Other important progress can be anticipated in research on subjective phenomena and on what is now being called psychophysics (e.g., the sense of time). Here quite radical mathematical models will be necessary. Finally, we can look forward to models that comprehend simultaneously both physical and behavioral events. If the history of the physical sciences provides any clue to what we might expect once adequate models become available, doors may open into areas of investigation and application that are as yet unknown or only vaguely perceived. Beyond these doors whole new branches of behavioral science may come into being.

Through such a door can be seen an apparatus that functions as a model demonstrating how neurons perform as units while simultaneously as a three-dimensional solid group they obey laws of wave motion based on electrochemical resonance phenomena. Larger models composed of aggregates of these neuronal clusters may even serve as true brain models. Meanwhile new materials (some already being developed) can be expected to permit semipermanent transectodermal pipes, tubes, and electrodes to be attached in transition between metals or plastics and biological tissues. Together with advances in immunology (promising soon to make successful homografts commonplace), we should anticipate eventual transplantation of either biological brain tissue or solid-state electronic modules capable of brain-type functions, powered by biochemical interaction with the physiological milieu.

Data Storage and Retrieval

Since general mathematical models, such as those proposed by signal detection theory, will soon be capable of organizing data from all aspects of information processing, the psychiatrist of the future will no longer be primarily required to conserve or reduce information. Electronic data processing machines will do that. Man's exploitation of the enormous storage capacity and speed of computers should make him more able to act primarily as a source of new information. This means a greater emphasis on creativity. In fact, today's new science of self-organizing systems can be expected eventually to evolve general models for the measurement and prediction of creative behavior in both man and computer.

Such models will contain general propositions capable of dealing with primitive elements (such as neural networks) as well as highly evolved ones (such as social groups and nations). Furthermore, in the evolution of man-computer systems the communication problem will significantly diminish. Instructions will be spoken to the computer, and verbal as well as visible responses will be obtained from it.

The decision-making process will shortly become a central issue in behavioral research. Born of the need for greater reliability in man-machine systems, current approaches to human information processing (as man senses, registers, stores, transforms, integrates, retrieves, and transmits information) will continue to develop

swiftly and will extend to social and even political applications. Today's beginnings (with concepts such as signal-detection theory, channel capacity, subjective geometry of the stimulus space, the "verbal-loop" hypothesis of encoding visual and auditory configurations for short- and long-term retentions, etc.) will lead to major new attacks on the problem of logical choice based on past experience. The purely human existential impasse, of course, will remain.

The psychiatrist of tomorrow will still be concerned with the immediate state of the organism, its most probable state at a specified future time, and the cost of its maintaining or improving current levels of performance. However, assessments will be made through increasingly accurate biochemical, psychophysiological, and behavioral monitoring. The output of individual glands such as a sweat gland (or the parotid gland; the secretion of which contains a fraction equivalent to blood serum) will be tapped and analyzed by advanced micro-methods and gas chromatography. Psychophysiological measures will employ on-line auto-correlation and cross-correlation techniques (e.g., spectral analysis) for predicting future states from ongoing data flow. Stochastic and Markovian statistical methods will lead to the development of predictable sequences of performance as they relate to sequential states of the human subject.

In this connection we must expect to break away from presently limited models for sequential analysis. These assume that input-output, stimulus-response, and man-machine relations are linear. This is related to the sister assumption that such systems are ergodic (i.e., that transitional probability relating state to state remains constant over time). However, ergodicity characterizes the state of man only briefly and only under special circumstances. Although most learning theory currently assumes constant attention, we already know that intensity and direction of attention fluctuate constantly in relation to both periodic and nonperiodic variables. As we employ more sophisticated models, rapid progress in psychiatric practice and theory can be expected to accompany sounder (albeit more complex) basic assumptions about man as a biosocial entity.

Psychophysiology

The present heavy emphasis on technical methodology in psychophysiological recordings will soon give way to more integrative types of analysis of relations between psyche and soma. Differentiation between stimulus-response specificity and individual response stereotypy will be simplified. The clinician will become increasingly interested in autonomic profiles. (Already, advocates of transcendental meditation are widely citing them!) The correct application of the law of initial values eventually should be determined for all autonomic measures, with a modified procedure for each, and with response intensity corrected by some function of the base level in every case. The resting autonomic profile will finally be understood as an interaction between the state of autonomic balance and learned behavior. Balance will probably emerge as a reflection of neurophysiological processes in the limbic system responsible for the individual's general emotional state. The response profile, on the other hand, will be understood more definitely as a function of learned behavior.

Tremendous progress is forthcoming in the analysis of psychobiological periodicity. More and more psychiatric interest will focus upon the mechanisms of variability in circadian rhythms and biological clocks. These and related observations will contribute to advances in the prediction, analysis, and control of behavior or performance. For example, research on diurnal periodicity has led to a growing appreciation of how sleep and its associated bioelectrical and metabolic rhythms—both fast and slow—provide a unique window through which to assess basic facts about the state of the organism. The implications for psychiatry are numerous and profound. Sleep analysis will soon be fundamental in research on psychopathology, in psychiatric diagnosis, and in following a patient's clinical course.

The psychophysiology of conditioning is fast approaching definition. Psychiatrists must begin to scrutinize the differential development of conditional responses during human life, with special emphasis on early experience and on transactions between the maturing brain and the changing environment that take place during so-called critical periods of growth and development.

Psychiatry's preoccupation with patients' pathological reactions to noxious stimulation and stress will be modified increasingly by consideration of positive consequences, such as the adaptation to stress through time. Our fascination with the psychodynamics of neurosis and psychosis must accommodate a greater emphasis on understanding the total biosocial dynamics of developing and maintaining good mental health. Thus we can expect increasingly active research on feelings such as joy, tranquillity, and satisfaction.

The investigation of cognition is moving toward the isolation of numerous variables and the establishment of nomothetic relationships among cognitive strategies, social cues, and memory information as they affect the formation of concepts. The identification of conjunctive, disjunctive, and biconditional associations will provide a better understanding of developmental factors in cognitive functioning. A model of cognition can be foreseen that will predict rates and types of information processing and higher levels of intellectual functioning, based on degrees of complexity, effects of social cues, and the functions of positive and negative feedback.

Problems of Consciousness

Progress in research on psychedelic drugs should lead to a resurgent interest by psychiatrists in problems of consciousness, including areas—such as epilepsy—long neglected. Ten years from now, every young psychiatrist will understand how to employ computerized EEG analyzers, as well as the corresponding successors to electromyography, electro-oculography, rheoencephalography, and the cortical evoked potential displayed by computers of average transients (CATs). These devices will be widely utilized in the study of problems of conscious-

ness and of other clinical problems, ranging from measurement of changing psychopathology to prediction of behavioral response patterns. The meaning of any given set of recordings may one day be obtained by processing it in relation to banks of analyzed and coded bioelectric recordings that will be centralized, perhaps at the National Institute of Mental Health, or as an extension of today's Medical Literature Analysis and Retrieval System (MEDLARS) at the National Library of Medicine.

Genetic and Biochemical Research

The genetic codes for any predisposing factors in the major mental illnesses should be deciphered in the near future. If so, the incidence of schizophrenia could be diminished by warning prospective marriage partners of the odds regarding risk to their offspring. Having identified a predisposed child, we might be able to diminish the likelihood or severity of schizophrenic reactions through improved child-rearing practices (e.g., continual close, affectionate contact between mother and child until he is past age three, with much handling, reality-oriented communication, and maximally undistorted interaction).[1]

Successful early diagnosis of onset (or recrudescence) of schizophrenia should soon be abetted by specific tests for pathognomonic psychophysiological reactions (e.g., increased electroencephalographic beta activity during REM sleep). Chemical tests for metabolic aberrations should also help. Perhaps the hypermethylation of biogenic amines will finally be confirmed as a manifestation of the acute phase of certain psychotic processes, thereby providing advance notice of illness as well as a clue to successful treatment. The present controversy over megavitamin therapy and the so-called orthomolecular approach may well revive the genetotrophic concepts of Roger Williams on a new and far more sophisticated level than was possible 20 years ago.

The symptoms of psychiatric illness, when they do appear, will be more and more modifiable through graded and symptom-specific pharmacological intervention. Even in the most disturbed or chronically hospitalized cases, severe ego disruption may be relieved by deliberately induced masking effects. The psychopharmacological revolution will continue to make possible important new advances in the chemotherapy of mental illness.

[1] Of course, the most difficult problem relating to the epidemiology of schizophrenia may turn out to be a paradox. With the growing emphasis upon ambulatory control of schizophrenics by means of drugs, there will be more carriers of the genetic defect abroad in the community. Even with relatively good symptomatic control, many of these people may suffer poor judgment regarding contraception and parenthood. This, combined with the relative skewing of the schizophrenic population toward poverty and ignorance, could mean an increasing number of genetically predisposed offspring. Furthermore, the predisposed children born to ambulatory schizophrenics will be less likely than the average child to receive the benefits of prophylactically desirable child-rearing practices by their handicapped parents. Thus, despite enormous progress in genetics, child development, and psychopharmacology, we may well be faced with an increasing schizophrenic population, concentrated more and more in the lower socioeconomic segment of society. This problem could pose a major challenge to social psychiatry in the future.

Research in Psychotherapy

Meanwhile, progress in research on psychotherapy will also be taking place. Computer analysis of the results of different types of treatment should eventually provide data permitting more precise prescriptions of appropriate therapy for patients of a given age, sex, intelligence, personality configuration, and nature and intensity of psychopathology. Today's relatively simple robot interviewing machines will lead to much more effective, extensively computerized devices capable of a high degree of response variability, and even of conducting procedures resembling individual psychotherapy, behavior modification, group psychotherapy, and group learning experiences for human subjects. Such approaches will also surely reveal and clarify those aspects of psychotherapy which must remain strictly human.

On-line recording and computerized processing of psychophysiological variables in both psychotherapist and patient during therapeutic sessions should yield further results in the measurement of transference and countertransference phenomena. We can expect to devise better maneuvers or combined methods (drugs, hypnosis, meditation, environmental manipulation, etc.) for facilitating the emergence of primary process material. It is not impossible that the sensory isolation tank or chamber will, in some difficult analytic cases, replace the couch. A continuing place for psychoanalysis is also foreseen, with a progressively evolving body of theory but with educational and research underpinnings shifting steadily from existing psychoanalytic institutes (which will remain as professional societies) to new programs in continuing education at universities.

Successful treatment of many drug addicts and alcoholics can be expected to utilize aversion syndromes (produced both instrumentally and by drugs), specific long-acting antagonists, and other biological augmentations to the necessary psychosocial commitment. Physiological components of addiction may come to be understood as resulting not so much from biochemical accommodation as from a heretofore poorly understood manifestation of the immune response, or specific reactions of cell assemblies in certain parts of the brain. This, together with studies on experimental addiction in animals, could lead to the emergence of a new concept of the biogenesis of addiction and a rational treatment for the craving states and withdrawal syndromes of addicts. If this occurs, some form of immunization against a specific addiction would not be out of the question. In fact, by combining addictive substances (such as opiates) with chemicals that block the addicting process, a marvelously extended variety of psychotropic substances could become safely available. Morphine, heroin, and synthetic narcotics might well be prescription drugs in psychiatry, if the danger of addiction were negated. Addiction, where it is still found in the future, should be attacked more effectively as a medical problem than has been the case in the past.

However, illicit drugs, even though they are not physically addicting, will continue to be a matter of major concern. Psychological dependency on drugs could well be-

come increasingly troublesome as psychopharmacology continues to advance. From thousands of relatively safe psychotropic substances that the pharmaceutical industry will develop it will be possible to achieve a great variety of altered mental states. These, according to the needs and desires of individuals, will be increasingly prescribed, sought out, or retreated into. Indeed, a debate may soon be raging among some clinical scientists on the question of whether clinging to the drug-free state of mind is not an antiquated position for anyone—physician or patient—to hold, when cheap, safe, specific, and pleasant psychotropic medications are readily available. Such a debate can be read in Aldous Huxley's 1932 novel, *Brave New World.*

As violence and antisocial activity continue to increase in the Western world, society looks to psychiatry for more help in these areas than we have provided thus far. Research on social conflict and life-threatening behavior will be given increasingly higher priority in psychiatry, with emphasis on analysis of the causes and prevention of racism, prejudice, class hatred, cultural deprivation, and violent crime. More effective treatment and control methods may be expected to emerge from continuing studies of group dynamics.

Psychiatry can also be expected to experience a growing preoccupation with character and behavior disorders. Longitudinal studies of differential child-rearing practices should yield important results. Thus research on offenders, including their reeducation and rehabilitation, will soon become a major multidisciplinary scientific endeavor involving psychiatry to a considerable degree. The prediction of dangerousness will be increasingly refined and quantified, although never, of course, perfected.

In sum, the greatest advances in psychiatry for the next two decades can be expected to come about through the integration and application of progress in fields such as genetics, biochemistry, pharmacology, neurophysiology, endocrinology, electronics, data processing, computer science, sociology, psychology, child development, and cultural anthropology. The psychiatrist will increasingly understand the genesis of psychoses, to a considerable degree the neuroses, and to a lesser but yet respectable degree the character and behavior disorders. He will have become oriented to integrative as well as analytic clinical research—fruitfully so for purposes of application in practice.

BARRIERS TO PROGRESS

However, there will be profound difficulties facing the psychiatrist in applying this knowledge. The shortage of scientific manpower will be critical. (The withdrawal and disruption of federal backing of research training and general research support are already producing effects that will be painfully felt for years to come.) Enormous social and economic problems will exist in relation to the population explosion and urban blight. Developments in atomic physics and solar power leading to cheap desalinization of sea water will cause major shifts of population. Industrial automation will produce more leisure time for more people, but not the wisdom or even the freedom to use that time to best advantage.

Further loss of family structure, diminution of parental sex-role differentiation, and greater mobility will probably be increasing sources of stress. Meanwhile, sweeping realignments of political and military forces throughout the world will be taking place. The expense of this will be added to the cost of continuing to explore the four corners of the solar system, the depths of the sea, and the bowels of the earth. All of this turbulence and flux will inevitably affect the life and career of the psychiatrist.

Nevertheless he will continue addressing himself to the mysteries of human nature in health and disease. Assisting him in this endeavor will be remarkable new equipment, including computers capable of duplicating many biological transactions, and a whole array of contributions from the field of bioengineering. He will be wrestling with the psychobiology of the most human aspects of learning, thinking, feeling, remembering, decision making, self-control, creativity, even ethical sensibility. The gradient of understanding in analysis of transactions among systems will still be highest with the smallest (e.g., atomic, molecular, and organic) but it will be much easier to move from these levels to those of organismic, group, and social transactions without changing languages—perhaps eventually without even having to change theoretical models.

THE PSYCHIATRIST OF TOMORROW

How will the psychiatrist be professionally occupied as all these changes take place? In my opinion he will become more and more firmly identified with the profession of medicine, which itself will be undergoing significant change. The psychiatrist of tomorrow will be much more of a neuroscientist than he is today; he will at the same time perforce become more of a social and behavioral scientist as well. The increasingly scientific roots of psychiatry, steadily replacing empiricism, will naturally necessitate substantial changes in education, not only for the psychiatrist, but also for other mental health professionals.

These allied helpers and colleagues must be considered in relation to the topic before us, because much of what is done by psychiatrists today will be done by others tomorrow. This trend can be seen throughout the field of health; many specialties are involved.

Thus one might predict that, in the relatively near future, most of the straightforward psychotherapy—both individual and group—will be done by clinical (or medical) psychologists. Social workers and psychologists with special training in sexology and group dynamics will be doing more of the marriage and family counseling. Community consultation on many mental-health-related matters will increasingly be carried out by experts from fields other than psychiatry: epidemiologists, applied sociologists, criminologists, specialists in community medicine, etc.

Hospitals, mental health centers, and mental-health-related community programs will be directed more and more by specially trained nonphysicians: executives with advanced university degrees in health administration.

In ten years educators, educational psychologists, school counselors, nurses, and even new paraprofessionals (e.g., mental health engineers) will be doing a considerable amount of preventive psychiatry. Ministers will be deeply involved in group encounter work. Meanwhile, a great deal of general office psychiatry, including the prescription of medication, will be carried out by physicians practicing specialties other than psychiatry: family medicine, emergency medicine, internal medicine, pediatrics, and obstetrics.

Psychiatrists, however, will be in greater demand than ever. They will be consulting with their colleagues in all of the foregoing activities, to provide the increment of additional expertise and depth that the true specialist should be expected to offer those with less, or different, training than his own.

Furthermore, the psychiatrist will be increasingly occupied with the complicated cases, the serious psychopathologies, the major mental illnesses. He will care for such patients largely in intensive psychiatric treatment units of general hospitals and also to a significant degree in mental health centers and relatively small psychiatric hospitals, both public and private. He will be using his own office for examination, diagnosis, referral, prescription of a wide variety of therapies (not only drugs) according to clinical indications and contraindications, and follow-up work.

Of course, the psychiatrist will also engage in office psychotherapy, but mostly of highly selected cases. These will be patients with difficult or severe problems—patients that the psychologist or family physician cannot manage. The psychiatrist will often be called upon to help with the patient whose physical disease has psychiatric complications, the dying patient and his survivors, the self-defeating or uncooperative patient, the mysterious or baffling case.

In his consulting work outside the hospital, again the psychiatrist will be called upon for his special expertise as the integrator of biomedical and psychosocial factors in preventing, comprehending, and ameliorating human distress. For example, I see a major and broader role for psychiatrists in relation to the care and rehabilitation of violent offenders, their victims, and the survivors of those who die by violence.

Thus the psychiatrist of tomorrow will be more of a neurobiologist, more of an endocrinologist, and more of a behavioral scientist than the psychiatrist of today. In fact, to educate him we must develop (among other experts) a new breed of behavioral neuropsychiatrist, much more biologically sophisticated than the teacher produced by the descriptive and organic schools in the past, and yet much more knowledgeable about psychosocial research than is presently the case. All this must be accomplished without yielding the hard-won expertise in psychodynamics that psychiatry has accumulated in the past 90 years.

THE CHALLENGE TO PSYCHIATRIC EDUCATION

Such a new global approach to psychiatric education might well be called *the biosocial approach*. The challenge it poses is profound.

Implications of this challenge for the medical curriculum, the medical student, and the psychiatric residency are obvious in terms of content and rigor. Much new material must be included at all levels, from premedical courses to the increasingly important postresidency programs of continuing education in psychiatry. However, to meet the challenge there are, in my view, some other implications as well.

These may best be formulated in terms of reactions to certain present trends, seen not only in medicine but in many facets of contemporary society, that many of us will welcome—reactions that are long overdue. I refer to reactions against haste, venality, sloppy craftsmanship, intellectual laxity, impersonality, creeping mediocrity, and cheap expertise.

Already we are beginning to see the emergence of a new major concern in our national consciousness—a concern with improving the quality of life. And, because medical education is part of our way of life, I shall venture some further predictions for medical education, as follows.

I predict the development of a new, well-rounded general curriculum for undergraduate medical students—a movement away from currently fashionable multiple specialized tracks. Five or six years from now, at some worthy medical school, a group of thoughtful young professors will develop a revolutionary plan. They will observe that virtually all medical students go on to become specialists. Therefore (they will reason) the medical school years should provide education to ensure the development of a man who is both a clinical scientist and a humane physician. He should receive a broad, comprehensive education in the basic biomedical, behavioral, and clinical sciences. He should also continue to learn much about man, his nature and his culture. Furthermore, he should pursue those humanities which can help make a physician more than simply a high-level health-and-disease technologist.

Well, then (the young professors will say), let's pack as much as possible into the undergraduate medical education of all physicians, regardless of what specialized tracks they get onto later. After all, they will have the rest of their long lives for specialization. It is *our* responsibility to lay the broadest, soundest general groundwork to ensure that every one of our graduates will be a true physician. In an age of specialists, let every physician be a bit of a Renaissance man.

I also predict the eventual restoration of the recent cuts in time required for premedical and medical education. All of that new material (described in the foregoing) will take some time to learn! Today we hear, "Get through premed faster; graduate from medical school sooner; get into your specialty as early as possible." Nevertheless, ten years from now I foresee a full four-year requirement for premedical education, followed by four additional

years for medical school, with educational *enrichment* rather than acceleration for the more gifted student. (Authorities on early education say that enrichment rather than acceleration is the healthiest approach in the primary grades; we might learn how to apply this wisdom in the medical school as well.) The young professors will say, "If we need more doctors, let's build more medical schools; meanwhile let's not cheapen medical education by abbreviating the curriculum, overcrowding the schools we have, short-changing the students, and debasing the intellectual currency of medical practice." The public (peculiarly sensible to its own best interest) will agree.

I further predict that the loss of the internship (particularly painful to many a psychiatric educator) will eventually be grieved by many who are currently shrugging off its passing. Sooner or later our brilliant young professors, taking a fresh look at the teaching hospital, will devise something dramatically new and different: a universal first-year residency that provides a general clinical background of experience, which is bound to be desirable regardless of subsequent specialization. They'll say, "Let every physician know something of clinical medicine outside his own specialty; he'll be a better colleague and more useful consultant as a result."[2]

Emphasis on Liaison Teaching

Within the progressive medical school ten years from now I see the psychiatrist teaching up-to-date psychopathology, diagnosis, and clinical therapeutics of the mentally and emotionally ill. However, I think there will be a greatly increased emphasis upon liaison teaching by psychiatrists in other clinical departments. Psychiatry finally will be taught on pediatric, medical, obstetric, and surgical services to the extent that was envisioned years ago by John Romano. Attempts to carry out such teaching have been made at Rochester and a few other medical centers through the years. But it may be that the development during the 1950s and 1960s of special psychiatric consultation services or circumscribed psychosomatic services actually stultified rather than fulfilled the dreams of Romano, Harold Wolff, Roy Grinker, Stewart Wolf, Franz Alexander, Spurgeon English, and many others. In tomorrow's teaching hospital the entire full-time psychiatric faculty should be actively involved in liaison teaching; nearly every member of the department of psychiatry should be attached (for several scheduled hours weekly) to one of the various other hospital service units. This I think will come.

Furthermore, I expect that in every medical school a division or department of behavioral science will, in addition to providing a substantial didactic curriculum, create similar liaisons with the basic biomedical sciences. Such arrangements will ensure that the behavioral implications of basic medical sciences become part of the education of every physician. In this connection my experience at the University of Oklahoma School of Medicine from 1954 to 1969 was highly instructive. Our behavioral science course (beginning in 1956) gradually expanded from 30 lectures in the freshman year to more than 200 classroom hours, plus much additional liaison and correlation teaching, through all four years of medical school. The course content was as rigorous as in other basic science courses. From the beginning it included the philosophy of science, psychophysiology, learning, experimental and social psychology, medical sociology, anthropology, animal behavior, growth and development, and human ecology. New material on psychopharmacology, sleep, neuropsychology, group dynamics, etc., was added as it emerged and the division of behavioral sciences grew and developed.

The results were excellent. In a few years Oklahoma medical students (then in the lower third of national board scores on nearly all subjects, both basic and clinical) had risen to the upper third in human behavior and in psychiatry. Even from the beginning, however, it was possible to forecast that "the behavioral sciences must be considered basic to the education of the physician of tomorrow if he is properly to meet his responsibility to his profession, to his patients, and to himself" (1).

I have already predicted the rise of a new neuropsychiatry. The neurologists must learn more about behavior; the psychiatrists, in their progressive rapprochement with the rest of medicine, must learn more about the brain.[3] The neuropsychiatrist of the future will, in keeping with the liaison concept, work closely with colleagues in the other traditional clinical disciplines and also with those in such new specialties as family medicine, community health, and emergency medicine, to mention only three. Thus not only clinical psychophysiology but family therapy, community mental health, and emergency psychiatry will be taught in conjunction with the steady movement of medicine as a whole into these areas.

THE LOCUS FOR TREATMENT

In closing I offer one final, if allegorical, prediction.

[2] The internship is scheduled to expire in 1975, doomed by the Millis report and the general unconcern of specialty training programs and boards. Meanwhile I, as well as like-minded psychiatric educators, still refuse to accept residents without a year's medical internship or its equivalent. But how can such an experience be obtained after 1975? Obviously through a resident year in a nonpsychiatric specialty. It is possible to arrange such opportunities, even if psychiatry must share the burdens involved.

Beginning in July 1973, UCLA will accept selected students straight from medical school into a four-year psychiatric residency. These individuals will spend the entire first year as physicians learning to treat physically ill patients under their own responsibility on medicine, pediatrics, and neurology services. At the same time they will receive considerable psychiatric supervision and instruction regarding the same patients. This is essentially an initial postdoctoral year of mixed medical internship/residency, with psychiatric enrichment, followed by three full years of psychiatry. The program is already oversubscribed. I hope others will develop similar programs, thus helping to make up for the loss of the internship, and to oppose certain current forces deflecting psychiatry still further away from the mainstream of medicine at the very time when we should be moving closer together.

[3] However, a newly amalgamated neuropsychiatry may not appear until after the American Board of Psychiatry and Neurology has finally split into two separate boards, since institutions seem to follow far behind ideas.

In the near future someone (perhaps at NIMH) will develop a brilliant idea about how to care for certain severely mentally ill patients. This innovator may very well win the Hoffheimer prize for the discovery that sometimes it is a mistake to take a mentally ill patient back to the scene of his disorganization. He will show that it is contraindicated to treat every patient in the community—perhaps an inner city maelstrom—where he broke down, where the strain was enormous, where unhealthy associations remain, where the pollution is poisonous, where the noise is deafening, where there is confusion and crowding and crime. Such a return, he will prove, may actually be antitherapeutic. He'll reason, "Wouldn't it be wonderful if such patients, who have collapsed under the overwhelming stresses of the megalopolis, could somehow be removed to a quieter setting? Let's find a therapeutic milieu of tranquillity, closer to the beauties of nature, far from the madding crowd. Maybe under more peaceful conditions these patients might have a better chance to recover, to be rested and restored before returning to the fray. Perhaps they might even be helped to find another way of life, one that would lead them away from that original high-risk community."

The question is, where are you going to find such a bucolic treatment setting in the future? As the cities continue to expand, the white collar workers move out to the surrounding countryside; industry moves out after them; and blue collar workers move out after the jobs.

But wait! A great location will unexpectedly become available. The bitter battleground that has been the ghetto—virtually deserted following the expanding concentric circles of centrifugal urbanization—this inspissated, unsavory bowel of the city will be demolished, plowed over, and planted. The only structure too new and expensive to be dismantled and transplanted in the suburbs will be the magnificent comprehensive community mental health center built in the inner city during the 1970s. Therefore, since it can't be moved, the countryside will be brought in to surround it in the former urban core, now a parklike retreat. Thus, perhaps by 2000 A.D., as in the Egyptian temples of healing 3,000 years ago, psychiatry once again will be where it belongs: at the center of things.

Questions of the Month

For each incomplete statement or question below, ONE or MORE of the completions or answers given is correct. Choose:

A if only *1, 2, and 3* are correct,
B if only *1 and 3* are correct.
C if only *2 and 4* are correct,
D if only *4* is correct,
E if *all* are correct.

Question 1

The National Institute of Mental Health is authorized by law to
(1) support through grants and/or contracts research into the causes and treatment of mental illness.
(2) provide grants for the staffing of community mental health centers.
(3) support training of mental health professionals.
(4) provide grants for the construction and staffing of mental retardation centers.

Question 2

The preferred treatment of nocturnal enuresis in childhood is dependent on which of the following?
(1) History of how it developed
(2) Availability of a conditioning apparatus
(3) Motivations of the child
(4) Results from a sleep EEG laboratory

(The Questions of the Month are from the Self-Assessment Program of the APA. The answers are supplied on page 553 of this issue.)

Western Humanism, Modern Liberal Politics, and Psychiatric Training: Friends or Foes?

BY ARNOLD J. MANDELL, M.D.

Liberalism once nourished the growth of an enlightened humanism upon the rigid constructs of analytic psychiatry. The New Left promulgates definitions of psychiatrists that are inimical to the basic postulates of psychiatry. They involve the nature of mental illness, individual responsibility for it, and the role of the professional in relation to it. American psychiatric education is challenged to train people who can cure the ills of society, but would be denied by the New Left the very tools with which we have learned to heal.

THE FIRST TIME a medical student explained to me that the disease of his socially disarticulated, paranoiac patient was a social role created by an oppressive society, I was startled. After his telephone calls to the patient's boss, union leader, and wife in the interest of gaining lebensraum for the victim, I felt confused. When he described the process of psychiatric diagnosis and the role of the psychiatrist as an example of the use of professionals as a social police force, I was irritated.

Increasingly, bright students, with good academic records, are refusing to accept the challenge of describing character in terms of the dynamics of personality; they tell me that such balanced, lyrical efforts are the masturbatory activity of the passive during this time of social change. Departmental laboratories of neurochemistry, behavioral biology, and neuropharmacology are viewed by many of them without interest; they say that they need time for community health organizing. Intensive and long-term treatment of psychiatric patients is merely a historical ritual; they want to learn crisis management and group therapy and to work in free clinics that they have helped to create through political action.

The educational process in psychiatry is becoming a vehicle for the propagation of philosophical, social, and political values. This is due in part to the kinds of students we are attracting and in part to the necessity of our reliance on subjective procedures and evaluations. The liberal position used to be an excellent matrix from which to try to modify the authoritarian superego that rules the neurotic. But the new liberalism, the New Left, has radical social change as its goal, and the institutions of psychiatry represent some of the most culpable features of the society that must be destroyed in order to build utopia.

Many potentially fine students who elect to concentrate in psychiatry, as well as residents already in training, manifest this peculiar contradictory commitment to psychiatry. I fail to see the merit in allowing a denigrating characterization of psychiatry to arise and prevail. Such a view can enhance neither the training received by young psychiatrists nor their later treatment of patients. What do they seek? Is the goal of training merely enfranchisement for greater social mobility and a more valent political image? I am always somewhat puzzled to see candidates with medical training running for elective office.

POLITICAL PHILOSOPHY AND PSYCHIATRIC PRACTICE

The line between the determinants of treatment based on scientific rationales and those based on the attitudes of social or political subcultures has always been difficult to draw. Early practitioners of psychiatry were shown by Hollingshead and Redlich (1) to be affected more by the features of their individual life history than by the features of their professional training. Right-wingers tended to wear white coats and use organic therapies. Left-wingers wore business suits and tended to practice psychoanalytically oriented therapies.

Admixtures of social, political, and philosophical concerns still struggle with technical considerations for dominance within our therapeutic strategies. Currently, personal responsibility, psychosocial determinants, definitions of sickness, and what Halleck has called "the power of the psychiatric excuse" (2) reign as the predominant issues in the field, and they probably determine therapeutic orientation more than any other factors, including efficacy.

APPLIED WESTERN HUMANISM

While the psychiatrist originally oriented to psychodynamics began to question the rigid concepts and procedures of his professional heritage, he continued to

Revised version of a paper read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The author is grateful to Dr. Marc Schuckit for the opportunity to discuss with him many of the thoughts contained in this paper.

value and to use the insights and attitudes that he had gained from it. This eclecticism gave him an orientation toward patients that was succinctly and beautifully described by Maas (3) as applied Western humanism. The modal psychiatric arrangements consisted of free communication within a matrix of relative permissiveness in a hierarchical dyad.

Gradually a neomorality that said, "Do no harm to others except for consenting adults," began to take the place of labels of sickness. The dignity of the person, his right to be unique, and the realization of his individual potential took their places as goals for the therapist. Against a culture that demanded conformity and discipline and a collective concern with identification of neurotic symptoms, humanism offered a combination of acceptance, insight, and consensual validation of reality. We felt that these values reduced anxiety and permitted patients more choices in the business of living.

Humanism thus applied does not appeal to all. Some view the problem of our age as akin to that of an individual with a character disorder, who feels little responsibility for others, little anxiety about the aspects of his behavior that might injure himself or others, and who suffers from a lack of meaning. Thus we have popular commitments to vogues like reality therapy. In contrast to the activities proposed by the New Left, such approaches basically confirm the spirit of Western humanism. In a way, they could only have become popular where humanistic aspirations held sway.

From the perspective of the New Left, however, the declared commitment of the humanists to the individual appears distorted. For one thing, the illness is seen as within the patient. It can be observed in relationships, or it might be hard to discern, but it will ultimately be found inside the mind of the individual. Not only is the disease internal to the patient, but the responsibility for its cure lies with the patient. External realities from his past and present might cause him a great deal of discomfort, and might even be etiological. Nonetheless, implicitly if not explicitly, the onus for change is upon the patient. Third, the therapist is acknowledged as the greater expert about the disease. The dyad, in spite of its permissiveness, is an authoritarian arrangement.

As nearly as I can determine, the student espousing modern liberalism is alienated by these three features, i.e., the internal locus of the disorder, the patient's responsibility to change, and the greater wisdom of the doctor. The idea of helping others to grow through their own self-realization is seen as patent nonsense. The current spate of nihilistic anarchy (thinly veiled with abstract and idealistic goals) consciously threatens the institutional arrangements that exist around the practice of psychiatry. We are hard pressed to know how to go about the business of teaching the listening and healing skills of psychiatry to these students.

THE PSYCHIATRY OF THE RADICAL RESIDENT

The manifesto of the New Left declares that an arrangement establishing the psychiatrist as the expert is intrinsically oppressive. Locating and placing the responsibility for dysfunction in the patient draws attention away from a guilty society. In the past such accusations came from gadflies like Goffman, Szasz, and Laing. Today some of our best residents and medical students claim that the very arrangements through which we teach and learn are the weapons with which the culture has victimized its now dysfunctional members. The meetings of the American Psychiatric Association have been challenged for the past several years by representatives of these victims of society and of psychiatry. The issues that they raise include the sexism innate to psychoanalytic theory, the application of psychodynamics to members of sexual subcultures, and the disregard of ethnic variables in our institutions and practices.

THE TASKS OF PROFESSIONAL ADOLESCENCE

I am not too old, nor is my memory too dim, to remember the identity crises that my fellow residents and I faced during our training. Practitioners in other areas of medicine have tangible tools to help them define their roles—scopes of one kind or another. Bereft of these, I was left with a pencil (not to be used until after the hour!) and my own musings during psychotherapy with which to draft a professional identity. I remember the struggles to achieve feelings of legitimacy. I desperately needed a firmly structured model. After experiencing the seductiveness of the pure psychoanalytic cosmology, I grew to espouse the peculiar eclecticism of applied humanism.

I was helped by my contacts with the professionals involved in my training. The psychoanalysts were theoretically rigid but could be flexible, warm, available, and adroit in their personal relationships. I encountered practitioners who were rigid in their personal relationships (and effective with certain kinds of patients) who preached theoretical eclecticism. I met some diagnostic purists and saw them make a significant contribution to the development of professional identity in residents. And then there was, of course, the grand, euphoric eclecticism which believed that no commitment to a single theoretical point of view was necessary if the individual therapist were secure. People were individuals, and one could choose methods from a wide store. Whatever worked was right.

Underlying all these options were definite consistencies. The profession of psychiatry was a helping profession. There was such a person as a sick patient. There was a professional setting, whether it was a ward, an office, or a living room. Community psychiatry was involved with the elements of the community that influenced the mental health of the individuals within it. But the paranoiac rage of the New Left threatens even these substrata. To them the society is the locus of the disease, the patient is the victim, many psychiatric settings are jails, and one's professional role is detrimental. Whereas the liberal politics of Western humanism can be integrated with the best fruits of conventional psychiatry,

it is difficult to imagine any kind of productive union with the philosophy of the New Left.

THE RESPONSE OF ACADEMIC PSYCHIATRY

We are left with a dilemma not unlike that faced by faculties in humanities departments in many universities in America today. There, too, members of the faculty and students involved in graduate education deal not with the accrual of appropriate background, knowledge, skills, and style, but engage in a struggle to establish whether the humanities should exist at all. In psychiatry it becomes increasingly clear that the major educational effort may be to win the struggle with the student about the legitimacy of the identity to which he aspires.

I have seen two types of response by faculty members to the intellectual challenges of the students of the New Left. When their own feelings of guilt or anger resonate with the students' concerns, they tend to identify with and share the nihilistic attitudes toward the traditional practices of psychiatry. I have seen professors in leading universities avoid discussions of brain chemistry, psychodynamics, clinical pathology, and development and participate vigorously in tirades against the institutions of society. Other teachers have responded by becoming more rigid and making formal efforts to keep people of radical social persuasions out of their training programs.

Another way to cope with the threat might be to define very carefully the legitimate scope of activities for psychiatry (perhaps more narrowly than one would like) and stick to those things in which we have historically claimed expertise, purposely impoverishing our areas of social and community concern so as to maintain our identity during this time of challenge. For example, it is tempting to train students in the new neuropharmacology, teach them effective biochemical treatments, give them some exposure to interpersonal sensitivity and psychopathology, and then describe them as the neurologists of behavior. We could then be few, and we could function as consultants for the primary clinical managers of illness. The need for such neurologists of behavior would not be great. Social activists would probably not apply.

It is a solution, but it is an impoverished solution. The other way, the route we are exploring tentatively in our young department, is to try the new direction to the left, to participate in whatever ways we can with the knowledge we have and see what we can make of it. We might find ways in which we could go to the community as instruments of change, using our conventional institutions and practices for larger social purposes. We might pragmatically exploit our role as professional givers of care to alter what we perceive to be social injustices.

Here on the left fork in the road we see chaos thus far. Community mental health centers in New York, drug abuse treatment programs in Boston, and some of the programs in Chicago (to name a few) are now defunct. Psychiatrists have proved inept when radicalized around social and political concerns. Our professional expertise has been downright inadequate in the sociopolitical arena.

I suspect that a factor in this could be the pressures upon us to abandon responsibility for the tasks and the milieus in which we work. We need not, it seems to me, wrench our roots from soil that has nourished us through several seasons of growth and embark upon some nebulous aerobic existence in order to cast a longer shadow. I would hope that we could effectively contribute to the prevention of social erosion by leaving our roots where they are, fertilizing them, and sending out new growth from a viable parent plant.

Our apprentices ask, more pointedly than heretofore, "What is psychiatry?" And they add, "Why is psychiatry? Should there be psychiatry?" The political and philosophical climate of our profession a few years ago provided an integrated liberal value system for therapeutic use. Now in its place in my younger colleagues is the angry nihilism of the New Left. This political matrix is not helpful to the healing art of psychiatry as we know it. Western humanism justified the psychiatrist's role as a kind parent giving nervous children the permission to live comfortably. The New Left projects a negative image of psychiatrists as the policemen of society. The most idealistic and altruistic role we can hope for in those circumstances is to be a spy within the police force.

The New Left seems to invade social institutions under the aegis of liberalism and then skew them to radical pseudoliberal goals; in so doing it discards the proverbial baby with the bath water. Western humanism and earlier liberal politics were the friends of practicing psychiatrists. The New Left shows itself, by deeds and by words, to be the foe of our old ways of being, and it challenges our relationship to our students in particular. The resolution of this issue is critical for American psychiatric education.

A Comprehensive Alcoholism Program in the Army

BY BYRON G. FIMAN, PH.D., DARYL R. CONNER, AND A. CARL SEGAL, M.D.

The authors describe the development and operation of a comprehensive alcoholism program at Fort Benning, Ga., that might serve as a model for community alcoholism treatment. The factors that seemed especially important in the success of the Fort Benning program were: establishing working relationships with medical personnel to provide physical examinations and detoxification services; offering a variety of therapies to meet patient needs; establishing an intensive treatment program that maintains community support and does not generate the kind of iatrogenic invalidism associated with classic inpatient care; introducing a systems approach to ensure comprehensiveness and continuity of care; fostering broad community involvement in planning and implementation; staff education and development; and involvement in bringing about changes in civilian and military attitudes toward alcoholism and alcoholics.

ALCOHOLISM HAS LONG BEEN RECOGNIZED as a significant problem among military populations (1, 2). Although there are few systematic studies of the extent of problem drinking, a recent government report (3) estimated that there are 130,000 alcoholics in the Armed Forces. Hansen (4), in a recent study of Air Force drinking patterns, suggested that on an age-adjusted basis there is somewhat more problem drinking in the military than among civilians. Catanzaro (5) reported that more than 20 percent of all psychiatric admissions to an Army general hospital were for alcoholism, a rate consistent with our own military experience. Coates and Pellegrin (6) have suggested that the attempt to achieve manhood through drinking may be partly responsible for alcoholism in the military. Other factors such as the boredom, isolation, and fear associated with military assignments, as well as such institutional factors as low-cost on-post liquor stores, service club "happy hours," and beer in the barracks and mess halls may also be important.

Preventive and treatment programs under medical auspices have not been systematically developed, although from time to time there have been programs in each branch of the military (7–10). Recently there has appeared to be a growing service-wide awareness of the requirement for more comprehensive alcoholism efforts, although there has been little formal recognition and support for innovative programs. The recently published *Alcohol and Drug Abuse Prevention and Control Plan* (11) may bring about the redefinition of alcoholism from a criminal act to a potentially treatable medical condition. However, significant efforts will be needed to establish treatment resources and to overcome long-standing reservations and negative feelings held by lay and medical communities in dealing with alcoholics (12).

We feel that wider dissemination of information about current Army alcoholism programs is necessary to promote further awareness of the problem and to facilitate the development of new programs in the military and civilian communities. We will describe the development and operation on an Army post of a comprehensive alcoholism program that we believe is unique in its commitment to the concepts of comprehensiveness, community involvement, and continuity of care. It differs from programs in other military services in that it was sanctioned, developed, and supported locally, with no organizational assistance from higher level commands.

PROGRAM DEVELOPMENT

One of us (A.C.S.) became Chief, Department of Mental Health Services (DMHS), at Fort Benning, Ga., in July 1967. At that time the post served a population of approximately 120,000, including 50,000 active duty troops. The DMHS was committed to the development of a comprehensive community mental health program emphasizing continuity of care, community-based treatment, prevention, and responsiveness to community needs.

By December 1967, it became apparent to us that alcoholism was a major factor in producing psychiatric casualties. Many patients were referred because of their own alcohol-related problems; others were referred because of family problems related to alcohol abuse. Therefore services were developed specifically for alcohol-related problems. A therapy group for inpatient alcoholics and their spouses was begun and quickly expanded to include outpatients as well. Several hours each week were set aside for new referrals with alcohol problems in order to determine the extent of the problem and the appropriate treatment strategy. The new services were widely publicized in the local medical community. However, it appeared that one or two therapy groups would have little impact on the alcoholism problem. Before a comprehensive alcoholism program including preventive and treatment services

At the time this paper was written Dr. Fiman was Research Psychologist with the Computer Support in Military Psychiatry (COMPSY) Project, Department of Psychiatry and Neurology, Walter Reed Army Medical Center, Washington, D.C. could be developed, substantial interest and cooperation would have to be elicited from major community elements.

During the next two years a number of efforts were made by the professional staff to enlist the support of major community leaders. While the efforts were unsuccessful, they served to alert senior military personnel to our concern with the scope of the problem in the community and the availability of beginning rehabilitative services. The latter included detoxification; individual, group, and family outpatient treatment; more extensive liaison with community agencies such as Alcoholics Anonymous; and community-wide publicity and educational programs.

In late 1969 the responsibility for coordinating a post-wide meeting on alcohol abuse was assumed by a retired infantry colonel. This seemed to provide the meeting with the credibility among the military that it may have lacked in the community. Significantly, the meeting was attended by every senior commander and staff member; most of these had sent their subordinates to previous sessions. The resulting steering committee that was formed examined various aspects of alcoholism in the community and received approval from the commanding general for the establishment of a comprehensive alcohol prevention and treatment program.

DMHS staff urged that a halfway house and social lounge be provided. Many patients had been held on the psychiatric ward long after their need for total hospitalization had passed because they needed more intensive care than the staff could provide on an outpatient basis. It also had become apparent that lack of an alcohol-free social facility contributed to recidivism: recovering alcoholics were forced back into the environment of military clubs. Although many seemed to go to the club more for companionship than for alcohol, social pressures often quickly led to renewed drinking. After a strong show of community support and assistance, suitable buildings and equipment were located and were ready for occupancy in March 1970.

DESCRIPTION OF THE PROGRAM

"Benning House" is the name of the entire alcoholism program in addition to being the name of the halfway house. The program has three major components: 1) treatment and rehabilitation, 2) education and prevention, and 3) research and evaluation. In an effort to ensure comprehensiveness and continuity of care, each component has been made interdependent with others.

Treatment and Rehabilitation

The major rehabilitative program is a 90-day voluntary residential experience. Residents live in Benning House, a remodeled troop barracks, but continue to report to their units daily to perform their normal duties. The staff consists of social work officers and specialists, chaplains, a registered nurse, graduates of the program, psychology and psychiatry consultants from the DMHS, and civilian volunteers.

The treatment process begins with the referral, which may originate in one of many sources—e.g., self, family, unit commander, chaplain, or hospital. The staff is on 24-hour call, so that referrals can be processed at any time. The initial interview, conducted at the site of the referral, is used to evaluate the appropriateness of the referral, determine if detoxification is indicated, and briefly describe the program to the prospective participant. If detoxification is indicated, he is admitted to a detoxification ward at the post hospital for three to five days, during which daily contact is maintained with Benning House staff. A staff member contacts an active duty soldier's unit commander or retiree's family in order to acquaint them with the functions of Benning House and to seek permission for the man to enter the program is he so desires. If detoxification is not indicated, after a full medical examination the individual is formally admitted as a Benning House resident.

At the first meeting with his staff counselor, the resident signs a contract stating that he understands the rules and expectations of the program and is participating voluntarily in the 90-day residency. This contract is not legally binding but serves to ensure informed consent by the resident and provides a tangible statement of commitment. The counselor also schedules the resident for a medical appointment to receive his prescription for disulfiram (Antabuse), which is administered daily to all residents unless it is medically contraindicated. As a rule, no other medications are prescribed during the 90 days.

A sense of responsibility for oneself is stressed by the use of the word "resident" rather than "patient." "Patient" often connotes an individual who is being taken care of by others and thus is not responsible for his own actions. The role of the Benning House staff is to facilitate therapeutic growth in residents, not to be responsible for it. The word "resident" is discussed by each new participant and his counselor until there is a clear understanding that the resident is ultimately responsible for not only his overt behavior in the program but also for his commitment to become authentically involved in the rehabilitation process.

The residency is designed to meet the needs of both the resident and his work unit by the scheduling of all group sessions after duty hours. This allows the resident to receive treatment and still remain active in the unit. The group sessions include one sponsored by the Fort Benning unit of Alcoholics Anonymous, a group led by the staff chaplain, a couples group where the focus is on opening lines of communication in an attempt to develop a new perspective in the resident's marital relationship, and encounter groups, which are directed toward enhancing self-awareness and interpersonal competency.

Standard treatment goals expected to be met by all residents do not exist at Benning House. Each resident is viewed as an individual with unique potentials and capabilities; treatment goals are contoured to fit his individual needs. However, all residents are members of the Resident Council and share equally in voting privileges. The Resident Council, which is self-governing (staff members are present only in a liaison role), evaluates and dis-

ciplines first offenders in cases of breach of contract (second-time offenders must go before the staff), provides recommendations to the staff for improving the treatment process, grants passes to residents who wish to leave the house over the weekend, is responsible for house maintenance, and generally regulates house activities.

Halfway through an individual's residency, an in-depth treatment review is held. This conference brings together the members of the staff with psychiatric and psychological consultants to review all available information concerning the resident's progress. The conference provides a systematic evaluation of progress and an opportunity to discuss alternative therapeutic interventions. Upon completion of the 90-day period the individual receives a certificate, signed by the president of the Resident Council and the Clinical Director, stating that he has successfully completed the program. "Postgraduate" outpatient services are also available.

Education and Prevention

Benning House has developed three major roles with respect to education and prevention. The first is to serve as a change agent to facilitate changes in attitudes and perceptions concerning alcohol abuse. As long as the problem is viewed as misconduct rather than as a treatable illness, little progress can be made in reducing the incidence of alcoholism in the Army. Therefore, a great deal of emphasis is focused on the idea that alcohol abuse is a medical and social problem that can be dealt with by a comprehensive treatment strategy, rather than only as a leadership problem that can be resolved through the use of severe disciplinary action. Each program staff member is assigned an area of the post and is responsible for initiating and maintaining working relationships with command and other unit personnel through a program of command consultation. There is evidence suggesting that the rapport established between project consultants and unit personnel is an important factor in the success of such a program (13). In addition, educational programs are conducted in conjunction with leadership training courses, at unit/battalion-level meetings, with hospital personnel, and in the school system for dependents.

A second role for Benning House is that of a linking agent within the health and social service delivery system in the civilian community. Attendance at community agency meetings, close liaison with local hospital facilities, and systematic follow-up of all alcohol abusers reinforce the idea that alcoholics are not ignored; the broad range of consequences within the community attributable to alcohol abuse also becomes more visible.

The third method is to provide a clearinghouse for information about alcohol and drug abuse. Staff members have appeared on local television programs and have been interviewed by several newspapers on various aspects of the program. Speakers from the staff are available to the military and civilian communities to discuss alcohol-related problems. Epidemiological surveys are furnished to commanders on the post to make them aware of the incidence and the demographic and behavioral correlates of alcohol abuse in their units.

Preventive services are generally conceptualized according to Caplan's description of primary, secondary, and tertiary prevention (14). Programs that disseminate factual material about the effects of alcohol and attempts to change attitudes about drinking as a symbol of manhood are seen as primary prevention, to reduce the incidence of problem drinking. Early case finding to identify abusers before their health and social supports have deteriorated irreversibly is considered secondary prevention. Programs to reduce residual disability (tertiary prevention) are undertaken to enhance the person's ability to function in civilian life and to ensure the availability of medical treatment for such conditions as brain syndromes, neuropathies, and cirrhosis to prevent further deterioration.

Research and Evaluation

With the assistance of the Computer Support in Military Psychiatry (COMPSY) staff, there have been two major types of efforts. One of these is a treatment evaluation system that can function as an integral component of the treatment process. This evaluation system has been designed but has not yet been implemented because of staff reluctance to maintain records that might cause damage to an individual's career.

The second effort is the epidemiological survey. A study has been completed estimating the level of incidence and attitudinal correlates of drug and alcohol abuse at Fort Benning based on the responses of 1,500 officers and enlisted men to a questionnaire (15). Data have also been collected on the degree of drug and alcohol abuse among 2,000 junior high and high school students in the area. Such assessments of the community provide the kind of information needed if we are to make informed decisions.

EVALUATION OF THE PROGRAM

More than 300 referrals were received for alcohol-related problems prior to the development of the formal Benning House program. No systematic case records or follow-up data are available, although highly visible examples of successful treatment were instrumental in mobilizing and maintaining community support.

With respect to the Benning House residential treatment program, data are available on the first 39 residents. (The maximum capacity of the house is 18; the number will be increased to 36 in order to accommodate the higher number of referrals as community acceptance increases.) All residents were male, mostly in the enlisted ranks (87 percent), on active duty (72 percent), and ranged in age from 19 to 61, with a mean of 40. Most residents were white (69 percent), had at least a high school education (66 percent), and were married (69 percent). About one-half were self-referred; the rest were referred by the resident's unit, family, or the hospital. Thirteen of the residents completed the 90-day residency program. Six were forced to withdraw because of family conflicts such as divorce proceedings in another state, and five withdrew because of orders to report to another post

or to retire from the service. Fifteen residents were dismissed from the program for drinking and not participating in house activities; they were perceived by other residents as blocking the program's effectiveness and were asked to leave the residential program. Successful residents usually continued in group therapy as nonresidents and participated in community activities. Two of them became counselors in the program. Unsuccessful residents were allowed to petition the staff for readmittance to the program.

While the number in the treatment program has been too small to allow for any conclusive statements, the demographic characteristics of the participants suggest several hypotheses that are important for future programs. First, all officers in the program were retired; none was on active duty status. This reinforces the notion that few officers will risk potential damage to their careers by disclosing their alcohol problem (10). Second, the percentage of black residents in the program was double the percentage of blacks in the post population. Blacks also had a higher rate of unit referrals than whites. This may reflect different racial patterns of drinking or the greater social visibility of blacks as problem drinkers. Third, almost one-half of the residents had a record of a previous arrest (49 percent). This suggests the usefulness of a systematic examination of arrest records, which might lead to early identification of a high-risk population who would serve as a target for primary and secondary preventive actions.

In addition to treatment evaluation, an important criterion of a comprehensive program is its ability to become identified within the community health and social service system as the agency responsible for drug and alcohol abuse and its ability to enhance and mobilize community awareness and support. As already noted, Benning House staff members have been invited to appear on local radio and television programs and to speak before various community groups. There have been more requests for community and medical consultations; requests for epidemiological investigations have increased; and staff members have been asked to teach aspects of alcohol abuse as part of the post leadership training courses. Staff members have testified before Congress (16) and participated in the establishment of a tri-service task force on alcoholism in 1971 in an effort to focus on institutional factors related to alcohol abuse. Such activities serve to enhance the areas of education and prevention and to broaden the potential impact of the program.

DISCUSSION

A number of factors can be identified from our experience as important to the development of a comprehensive alcohol program. One is the identification of core staff willing to become interested in alcoholism, to put aside old stereotypes, to learn about alcohol and its medical-social roles, and to relate to people with alcohol problems.

A critical factor is broad community support. Resources for innovative programs are difficult to obtain and especially hard to justify when a "bunch of drunks" are recipients of benefits during a time of declining troop strength. The community requires education to revise its attitudes about the nature of alcoholism in order to become aware that preventive and treatment programs can produce valuable human and economic results. At Fort Benning, field commanders, lawyers, chaplains, clubwomen, physicians, noncommissioned officers, and personnel specialists were brought together in sessions designed to broaden their understanding of problem drinking. They were made aware that only a small percentage of alcoholics fit the classic "bum" stereotype—that most people with drinking problems hold jobs and have families and that intervention with minimal stigmatization offers the greatest chance for success.

Also important is the need for staff stability. For the past few years the Army has experienced massive personnel turbulence. However, adequate time for staff and community development and for continuity of goals seems essential. If the military is to approach the problem of alcoholism with the seriousness it deserves, high priority at the service level must be placed upon duty stabilization of program staff.

Male Transsexualism: Uneasiness

BY ROBERT J. STOLLER, M.D.

The author discusses sex reassignment in men. He points out that since 1953, when the procedures were first publicized, attitudes toward granting "sex change" have become increasingly liberal, resulting in a dearth of knowledge about the number of men who have received hormonal or surgical treatment; the frequency of surgical and postoperative complications and of morbidity and mortality; the nature and frequency of psychiatric complications; and the percentage of those treated who have benefited. Believing that sex reassignment should be restricted to the most feminine men, the author urges more scrupulous follow-up studies and more careful consideration of requests for change.

THE CARNIVAL ATMOSPHERE PREVAILING in the management of male transsexualism may have been unavoidable considering what a spectacular aberration this condition is. At any rate it is too late to back up. By now probably a thousand or so males have been "sexually transformed." (We shall never know exactly how many because of the clandestine arrangements used by some surgeons.) Should time prove that the rate of untoward results is acceptable in terms of the severity of the condition, then we shall rest comfortably, and such procedures will become an unremarkable part of medical practice. But while we await these follow-up studies, there is reason for uneasiness.

First, let me express the opinion, which is in disagreement with those who feel that "sex transformation" is never indicated, that there are extremely feminine males who can effortlessly pass undetected in society as females and for whom no known treatment exists that would render them masculine in behavior and appearance. In the absence of any such treatment we have three choices: 1) insist, nonetheless, that they be treated by some method which does not work (e.g., psychoanalysis); 2) do nothing, with or without moral exhortation; or 3) provide them with "sex transformation." I favor the third option for these patients.

COMPLICATIONS

The issue is complicated, however—more so than is usually acknowledged. Some years ago positions were polarized: A small number of physicians favored helping patients change sex roles, while a majority of people (of particular importance the medical profession, including psychiatrists) were opposed (1). Now, publicity and showmanship have reversed opinion, with a large part of the public and the medical profession comfortably, and unthinkingly, accepting the treatment.

Here the first complication arises: The patients themselves announce the diagnosis of transsexualism and expect physicians simply to perform the mechanics necessary for altering their bodies. This is odd, but more distressing are the referrals from medical colleagues who fail in their responsibility to diagnose the patient themselves but, rather, accept him as a transsexual simply because he has requested sex transformation. These physicians then want psychiatrists to arrange for the treatment; imagine: a diagnosis based on the treatment the patient recommends. This is terrible medical practice, mitigated for me only by the hope that it makes no difference who is "transformed" *if* all have happier lives. But we do not *know* that yet; we can *suspect* that some patients are not doing well postoperatively.

Following is a hypothesis that can be tested if proper follow-up studies are done: The more masculine a patient's appearance and behavior as an adult and the more masculine episodes he has had from earliest childhood on, the more likely he will have a psychic disorder after "sex change."

A second complication results from issues of diagnosis. Some believe transsexualism is fictitious, invented to permit homosexuals to escape their responsibility for being nomosexual (2) or to prevent the unmasking of a psychosis hiding behind a clever delusion (3, 4). These positions grow from the inadequate criteria used to define transsexualism. There must be a more admirable way to diagnose this condition than to say a person is a transsexual because he requests sex reassignment. I would rather attempt to diagnose by assessing the degree of femininity and its length of existence. To put this differently, how firm is the patient's conviction that he really is a woman trapped in a male body?[1] Since it has already been done elsewhere, I shall not describe the clinical, psychodynamic, and etiological features that help me make the diagnosis of transsexualism (5, 6). A sketch may suffice if the reader keeps in mind that a more complete ar-

Read at the joint meeting of the Danish Psychiatric, Psycho-Analytical, and Psychological Societies, Copenhagen, Denmark, May 4, 1972.

Dr. Stoller is Professor, Department of Psychiatry, UCLA School of Medicine, Los Angeles, Calif. 90024.

[1] Of course, those of us faced with the task of diagnosing transsexualism have an additional burden these days, for most patients who request sex reassignment are in complete command of the literature and know the answers before the questions are asked.

gumcnt is to be found in these longer reports.

I have found the greatest femininity in males among those who have been feminine since earliest childhood and in whom no stage of masculinity has ever been observed. In such cases the mother has had a lifelong sense of worthlessness about being a woman that has driven her to want to be a male so intensely that during preadolescence she may almost have seemed a female transsexual. Following the changes of puberty, such a woman gives up hope and in time marries. Her husband is a distant, passive man and is never around the house to serve as a masculine presence. If this mother gives birth to a son who she feels is beautiful and graceful, she establishes an excessively close symbiosis with the child that excludes the father and persists for years. As signs of femininity appear in her son in the first year or so, she encourages them while snuffing out the slightest behavior she interprets as masculine. And so a genuine femininity is encouraged to appear from the first. It may not surprise us then if the son of such a person requests that his anatomy be changed to conform with his sense of himself as feminine.

To summarize my position regarding male transsexualism, if there is a group of people who more or less have the same clinical picture, dynamics, and etiology, one can properly consider them to belong to a clear-cut diagnostic category. Issues in treatment and in the search for etiology are only confused, however, if one throws many different clinical types into the same pot simply because all share one striking feature in common, i.e., the request for a sex reassignment, when they fail to share other features (6).

The following examples may illustrate my point.

CASE REPORTS

Case 1. This patient is the divorced father of two children, in his 30s, and in a profession that is practiced only by men and in which signs of femininity would lead to professional disaster. His appearance is masculine, not only because he is 6 feet 5 inches tall and weighs 250 pounds, but also because he is unable to carry himself in a feminine way. Nonetheless, since early adolescence he has secretly dressed for an hour or so at a time in women's clothes, becoming sexually excited and then masturbating. Despite his masculinity, he has recognized a wish to be a girl since mid-childhood. Beginning in adolescence, when he first started dressing in his sisters' or mother's clothes, he has told himself that he has two aspects, a girl's and a boy's. He has experienced the greater part of his life as a masculine-appearing man, inhabiting a male body; however, when he puts on women's clothes, he feels that he is a woman (although not a female) and that he has a woman's name. He does not believe that "sex change" will remove that part of his identity which is a man. Nonetheless, he demands this treatment since he believes his feminine aspect is enslaved inside his male body.

For years the patient could manage with intermittent cross-dressing; however, even though this was sexually gratifying, he began to yearn to reveal his femininity. Frustration of his desire made him severely anxious, and at times he slipped into a paranoid state with persecutory delusions. His next attempt at a "cure" was to try to find a masculine homosexual woman who would want to be transformed into a man and to marry her; then, each would trade roles. When he could not arrange this, he began thinking of sex reassignment. Not yet motivated to go through with the operation, however, he married, hoping either for a cure via heterosexuality or by spending more time in traditionally feminine activities, such as his wife's household chores. Although he could get erections and fathered children by fantasizing he had a vagina, this attempt—marriage—failed also.

With his marriage, the patient stopped seeing me. A few years later, he wrote to request an interview. A few minutes before the appointment he appeared, looking ashen and in shock. He had just incised the base of his penis in the bathroom across the hall. When the emergency was resolved, he told me how he had planned this exploit for weeks, having studied the anatomy of his genitals so he would not bleed to death inadvertently. He had hoped to force me, and thus the medical center, to give him an operation, although we do not have a program for such surgery.

Since the patient and I had always had a good relationship, I felt comfortable telling him that I would not be blackmailed in this matter. He apologized for having placed me in such a position but added that without the operation he would, regretfully, either blow up an airplane or poison the water supply of Los Angeles; he may have been technically equipped to do both of these. In addition he could barely resist running girls down with his car as they crossed the street to school.

Not forgetting his paranoid tendencies, I told him that on further consideration I could be blackmailed. This consisted of my condoning his dressing more frequently in women's clothes, prescribing a progesterone derivative (that has minimal feminizing effects), and standing aside as he worked to save money for the operation. Recently he arranged with a private surgeon for genital surgery. He calmed down, and the two years he has spent in this manner have been the happiest of his life. He bought a wig and women's clothes and for the first time began wearing them publicly during the day. He looks grotesque, but he is thrilled. Despite his mass, the blonde wig that does not fit, the bizarre makeup, the bulky walk, and his inability to carry himself in a feminine manner, he acts convinced that people think he is a normal female. He never appears at work as a female and has raised no suspicions there. In fact, the happy calmness that has overtaken him has led to the first professionally successful period in his life.

He says that after the operation he will continue to work and to spend his days as a man but that he can survive only if he has occasions to live as his womanly self. Let us hope he is right; this will be a better solution than another paranoid psychosis.[2]

Why call this patient a transsexual?

Case 2. This patient, who is in "her" 30s, divorced, and the father of two children, lived exclusively as a man until a few years ago. Having sensed a feminine quality since mid-childhood, he intermittently dressed in women's clothes throughout his teens, always becoming sexually excited. He lived for a few years with another man in an avowedly homosexual relationship in which he played both the masculine and feminine roles but preferred the feminine role. During his years in the military service, he had several homosexual affairs. In addition, he created and built a full-sized artificial man, which he kept hidden in an apartment. He made love to this man when-

[2] Beyond what I have said here, one may wish to contemplate further the morality of condoning a procedure with this patient because he threatened murder.

ever he could, placing the man's arms around him in an embrace and putting the man's penis in his anus. The patient also obtained pleasure from heterosexual affairs, and eventually he married.

In his late 20s, the patient spent several years as an armed robber whose spectacular feats were headline stories. This attempt to be manly ended when he was finally arrested; he spent many years in prison, during which time he decided that when freed he would live as a woman. I first saw him shortly after his release.

In time, he arranged for "sex change" and returned thrilled with the anatomical and psychological results. Although over six feet tall, he is sufficiently graceful to pass successfully as a woman, has been steadily employed, and has had boyfriends.

Should this patient be called a transsexual? Socarides reported the case of a similar patient whom he represented as the prototypical transsexual (2).

Case 3. This patient in his late 30s is married, the father of three children, and successfully employed in a typically masculine profession. He has never cross-dressed in his life, has never become sexually excited by handling women's clothes, and has never had homosexual relations. However, in recent years he has decided that he must have his genitals removed. During this time, he occasionally took estrogens, but whenever his breasts enlarged and his potency decreased, he became depressed thinking how he was hurting his wife. He finally decided to have the operation and to divorce his wife but still to support his family. He says he has no intentions of living as a woman.

Is this patient also a transsexual?

Case 4. This married man has never held a steady job because he has suffered from a schizophrenic thinking disorder since he was a teen-ager. When he was in his 20s, he decided he was a female. Nonetheless, he married a woman older than he was, because she felt she needed a husband. They had intercourse for a few months but ended this by mutual consent.

For ten years the patient wished for sex reassignment, insisting that he was a female. Unable to arrange for this, he moved away from Los Angeles; I have not seen him again. However, I did receive a letter from him in which he described how he had meticulously surgically removed both his testes in his bathroom. (The patient had had practical nurse's training.)

DISCUSSION

The list is endless. Anyone doing research on this subject has seen numbers of such people with the most varied personalities, having in common only their belief that a part of them is so feminine that it can be fulfilled only by "sex change." Some of these patients are primarily fetishistic cross-dressers; some, primarily effeminate homosexuals; some, primarily psychotic. The possibilities are endless. But if by inexorable logic they are all called transsexual and if that label is currently the only permit needed to grant sex reassignment, we have failed those patients for whom the operation is dangerous.

This detour into diagnosis promotes my argument: Until careful follow-up studies provide more adequate answers concerning who can safely be subjected to this massive surgical and psychological procedure, the most conservative and humane way to proceed, I believe, is to restrict "sex change" to the most feminine males. I believe that other workers can confirm my experience that all such patients pass silently, completely, and permanently into society as women.

Even if my proposition regarding etiology is wrong, perhaps this rule would still be the proper one to use. For instance, should it be proven that there is a specific biological cause for transsexualism, the wisest choice might still be to restrict the operation to the most feminine of males. They certainly give one the feeling that their femininity is firmly fixed and that their maleness can have no value to them.

Among those requesting help then, on whom should we not operate? I think that for the present time (although clinical judgment may force such rare exceptions as in case 1), we should exclude those who are psychotic, who have had psychotic episodes in the past, who are sorely depressed, who have had severe depressions in the past, who are currently married and have families, who have been married and were able to engage in intercourse with erections and orgasm, who appear to be masculine (by this I do not mean body build so much as manner of dress and behavior), or who for extended periods have appeared to be unremarkably masculine. We should also exclude the large group whose members, despite an ability to intermittently appear as feminine, have revealed throughout maturity that their genitals give them pleasure (e.g., fetishistic cross-dressers and effeminate homosexuals).

The rationale underlying the inclusion of this latter group of subjects (by far the largest number of people requesting "sex change") is that these men have significant, demonstrable masculinity and sense the value of their genitals, however much they also abhor them. In other words, these men have a history of valuing what they now propose to give up. One need not be a psychoanalyst to have seen people with ambivalence, one part of which is hidden until the other part is removed. Since it can be difficult to determine how highly a person prizes a given aspect of himself at a time when he denies it at the top of his lungs, we run risks in presuming that there is nothing of value to be lost. Until we can replace an amputated penis, we must be careful. Some physicians are familiar with the patient who has convinced a surgeon that "sex change" is indicated, indeed crucial; and yet the patient discovers postoperatively that he has made a mistake from which he cannot retreat. It is under these circumstances that we see the onset of psychosis, depression, suicidal intent, hopelessness, male homosexual prostitution, and even medico-legal complications.

Undoubtedly, however, there are many males, like those in my case reports, who would do better if granted "sex change." The problem is that we do not yet know how many will improve and how many will be harmed. We ought not be indiscriminant but, rather, we should establish criteria for accurate prognosis, not relying on anecdotes of good results and not minimizing those of bad results.

Now that I have rigorously restricted the diagnosis of transsexualism and suggested that we only operate on those who fit this diagnosis, how will we ever know what happens to the rest? With a bit of effort, we can probably obtain our answers from among the thousand or so such people already in society. Or we might set up an experiment to be carried out only by those medical centers in various countries which would be medically and scientifically responsible. In this experiment we could match categories reflecting the different clinical pictures, e.g., the transsexual, the transvestite, the effeminate homosexual, the mixed type. If only those who seem the most highly motivated were treated, we could then determine, with proper follow-up, whether those in one category did better than those in another or whether these concerns with diagnosis were not significant in the end results.

Can one argue that even without follow-up studies we can proceed without hesitation? This is how the medical profession has acted despite the example of such scrupulous teams as that at Johns Hopkins. At the least, changing a person's sex is no minor, benign surgical procedure, but rather one with significant surgical risks and with frequent postoperative complications. Any other new and potentially dangerous surgical procedure would have been tested more thoroughly. But there is something about the person who requests sex reassignment that brings out or attracts a lower level of medical performance in all areas of evaluation and treatment.

"Sex change" has profound implications that touch on everyone's vulnerability to magic; and in the management of would-be transsexuals the magic and mystery of the condition seem to act as an excuse for relaxing normal medical prudence. Worse, the treatment attracts some who are not medically prudent to start with. We all know of surgeons who are willing to operate as long as the price is right; they seem scarcely concerned even when they are inexperienced. We know of psychiatrists as well as other physicians who put themselves in the position of psychiatrists whose only criterion for recommending surgery is the shrillness of the patient's request. They are unconcerned about and unequipped to properly evaluate the patient's personality; they are equally uninterested in doing the follow-ups we so badly need. So far, there has been almost no protest about this state of affairs from those of us who know these patients best.

CONCLUSIONS

Since 1953, when procedures for "sex change" were first publicized (7), an unknown number of males have received hormonal and surgical treatment on request. That we have no notion how many have been treated when the procedures are experimental and potentially dangerous is astonishing. That we do not know, almost 20 years later, how the patients fared is scandalous. Only two workers have reported careful follow-up studies of more than single cases.[3] In 1969, Randell published results on 29 males and six females (9), which he extended in 1971 to 44 males and eight females (10). The Johns Hopkins team, the first to set up a well-planned program for sex reassignment, has published one report on 17 male and seven female patients. Originally done in German in 1970, Money later summarized this study in English (11). We do not know the frequency of surgical complications, postoperative complications, morbidity, or mortality. We know little of the nature and nothing of the frequency of psychiatric complications. We do not know what percentage of patients benefit from the procedures nor has anyone even published a competent rating scale to assess benefit. Except for anecdotes, we do not yet know what the passage of years does to these patients.

This is too primitive.

Can we not devise ways to control this runaway process? I believe that setting up programs for treatment ought to be the responsibility of the university medical centers—I think these experimental procedures should be restricted to the universities—not only to practice the finest medicine and to develop proper instruments to measure pre- and postoperative results, but also to exert effort to prevent incompetent and uncaring practitioners from treating these patients.

Finally a closing thought: the conclusions in this paper hold for females as well as males.

[3] Benjamin also has reported his impressions, but he did not try to establish precise criteria for rating the results (8).

Playroom Setting for Diagnostic Family Interviews

BY IBRAHIM N. ORGUN, M.D.

The author describes the use of a playroom setting for diagnostic family interviews in which play therapy and family interviewing techniques are incorporated. By using this method the diagnostic team can accumulate valuable diagnostic data on the family, while causing the least discomfort and stress to the children. The method also acquaints the parents with the use of the playroom and play materials in play therapy. After having used this technique for two years, the author believes that it could easily be adapted to family therapy for families with young children.

THE CONTRIBUTION OF FAMILY INTERVIEWS to the diagnostic understanding of the family and the identified patient is well established. However, the role of younger children in family interviews conducted on a verbal level has not attracted much attention. Those familiar with children and child development are well aware of the difficulty and discomfort that children younger than ten years of age experience in family interviews that are conducted in an office, where the primary mode of communication is verbal and on the adult level. These same children, however, find the playroom and play material conducive to communicating their conflicts and feelings. This consideration, combined with the aforementioned concerns, makes the playroom an ideal setting for interviewing families with children ten years of age and younger. In our experience with 70 families, even some children between ten and 12 years of age felt more comfortable in a playroom setting.

REVIEW OF THE LITERATURE

Having a parent, especially the mother of the child patient, in the playroom is not new. Schwarz described the psychoanalytic treatment of two children while their mother was in the playroom (1). Pappenheim and Sweeney treated a child with the mother in the playroom because of the separation anxiety that both the child and the mother experienced (2).

Others included home visits in the diagnosis or treatment of children. Bornstein treated a two-and-a-half-year-old child by visiting the patient at her home (3). Freeman found home visits to be very valuable in diagnosing children (4).

Dr. Orgun is Associate Director, Child Psychiatric Services, the Institute of Living, 17 Essex St., Hartford, Conn. 06114.

Drechsler and Schapiro (5) described a three-step family interview procedure that included: 1) a psychiatrist's interviewing a family in a playroom while a psychologist observed through a one-way screen; followed by 2) a ten-minute period when the family was left alone while the psychiatrist and psychologist observed through the one-way screen; and 3) a final period when the psychologist introduced a questionnaire and remained with the family as they answered it while the psychiatrist observed through the one-way screen.

Augenbraun and Tasem (6) described two different techniques of family therapy for preschool children and their parents in a play-therapy room. Differences in techniques were related to the makeup of the parents, specifically whether they were neurotic or borderline and psychotic. Bergel and associates (7) presented the use of play materials in conjoint family therapy. Ackerman (8) aptly dealt with the importance of the child's participation in family therapy and suggested techniques to ensure it.

Our approach comes close to the techniques described by Augenbraun and Tasem (6) and by Bergel and associates (7). However, it differs from theirs in that it uses the child's play and activities as a starting point and focuses on the child's communication. In short, communication through play activity and material constitutes the primary communication mode, at least for the children.

THE TECHNIQUE

The diagnostic family interview is part of the diagnostic process, which also includes interviews with the parents, individual interviews with the child, psychological testing, and, when indicated, electroencephalography. During their individual interviews with a social worker and a child psychiatrist the parents and the child are each told that they will be seen as a family so that the diagnostic team can get to know how the family functions. The family diagnostic interview is held about a week after the child's psychiatric interview. The social worker and the child psychiatrist meet with the entire family in the playroom. The child, who is familiar with the clinic setting, is frequently asked to lead his family there; his handling of this task offers diagnostic clues.

Our playroom has enough chairs for adults and teenagers. The family members choose their seats; how they seat themselves gives clues about the sidings and groupings in the family. Once the older members of the family are seated, the members of the diagnostic team place themselves among the family in a way to make it possible

for each of them to observe and interact with all members. We have found that if the team does not initiate the interview by making a verbal statement, there is a better chance for the interview to proceed on play and activity levels; any verbal statement from the team tends to communicate that the interview should proceed on an adult verbal level. However, in cases where prolonged uneasiness and anxiety are experienced, the original statement that the team wanted to see the family together is repeated. In the majority of cases, the child patient or the siblings have begun playing and the interview has proceeded smoothly. If the children did not play or interact with each other and the adults, we have found that it was more revealing and effective to explore the reason for this with the parents than to encourage the child to play. An example follows.

Case 1. A ten-year-old boy, Michael, who was referred because of poor school work, throwing away his books, general disobedience, and running away from home, was seen in the playroom with his divorced mother and his eight-year-old sister, Nancy. Both children sat rigidly, without moving; they glanced at their mother. When this was pointed out, the mother indicated that the children never did anything unless she told them they could. With her permission they started to play, but even then they waited for her nonverbal cues as they moved from one activity to another.

As an interview proceeds the social worker and psychiatrist move around and, if invited, join in the children's play. They interact verbally with the older members of the family, inquiring about their reactions, feelings, or interpretations of the child's interaction or activity. They may encourage the older members of the family, especially the parents, to join in the children's activities. The interaction in these instances is quite revealing.

Case 2. A six-and-a-half-year-old boy, John, his four-year-old sister, Judy, their mother, and their stepfather of a few months were interviewed. At one point the stepfather complained that he wanted to do things with John but that the boy rejected his offers. A few minutes later, John asked him to play a game. First the stepfather, who accepted this offer, remained seated in his chair while the boy sat on the floor. This created a gap and made it uncomfortable for both.

At one point both of their playing pieces landed on the same square, the stepfather's arriving last. The stepfather told John that he had to go back to the start. The boy insisted that the rules contained no such move, but the stepfather would not accept this. One of the diagnostic team members suggested that they might want to read the rules. However, the stepfather did not take this suggestion, the boy stopped playing, and communications broke down. At this point, the mother took the game cover that contained the rules and read them. Realizing that her husband was wrong, she seemed to become very angry. But paralyzed with anger, she put the cover back without saying a word.

Frequently the child psychiatrist interacts with the children and a social worker interacts with the parents. However, these roles are switched as often as the team sees it is necessary during the 50-minute interview. As the interview proceeds, the play and verbal interactions among the members of the family are observed and scrutinized.

While observing John and his sister Judy, mentioned in case 2, one of the team members overheard Judy say to her brother that she had the white wooden doll. (They were both playing with different colored dolls; there was only one white doll.) As soon as Judy said this, John grabbed the white figure. The little girl began crying and protesting. The mother, not realizing that Judy had initiated the interaction, scolded the boy. In this instance, we should see the little girl's manipulation and understand why the boy struck out at his peers and those adults who tried to control him.

The team comments on the nature of divisions, sidings, and conflicts among the members of the family. At the end of the interview they attempt to relate the presenting problem of the patient to the family and to explain its functioning.

FINDINGS AND CONCLUSIONS

Two years of experience have shown that use of the playroom for diagnostic interviews of families with young children leads to the unfolding of more diagnostic data in a much less stressful atmosphere than an office setting. The children find the play material conducive to revealing information, some of which may be important.

Case 3. In a family interview that included the patient, Larry, age 12, his sisters, ages ten and five, and their separated mother, the ten-year-old created a violent fight between the mother and father puppets. At the end of the fight the mother puppet asked the father puppet to leave and to take the children with him. Since the mother had told us she did not know why her husband had left her, this piece of play activity was very revealing.

By meeting in the playroom, the adults communicate their willingness to listen to the children. They enter the child's world and meet him on his level. Meanwhile the diagnostic team observes the interaction between the parents and children and among the children themselves, which is very much like that in everyday life. In an office setting we only hear about this interaction or, at best, listen to its verbal aspects.

Case 4. At the beginning of this family diagnostic interview centered around a six-year-old boy named Richard, who was known to have coordination and learning problems, his father asked him to draw his (the father's) picture on the blackboard, thus setting a goal that could not have been attained. As the child struggled, the father made manifest his disappointment on the one hand and his inability to accept the child's limitations and to support him on the other.

Since the material revealed by the children is through play and activity, the examiner can choose not to focus on it in order to keep the child from becoming anxious. In contrast, the child cannot be protected from discomforting anxiety in an office-type interview. When an anxiety-provoking situation does take place in the play-

room, the play material is available to help the child deal with his anxiety.

Judy (cited in case 2) found the little girl and father puppets helpful in dealing with her anger and anxiety over the disagreement between her brother John and her stepfather about the game rules. She made the little girl puppet hit the father puppet, saying, "Don't hurt my brother."

Playroom equipment offers situations that may be helpful in understanding the parents' personalities as well. For instance, parental reaction to finger paints and aggressive toys like guns provides us with opportunities for better understanding that could not be duplicated in an interview held in an office setting.

Case 5. After observing her son's attraction to a toy gun, the borderline mother of four-year-old Jimmy, who was referred because of aggressive behavior, expressed her disapproval and with it her own problems with aggression. She reproached the child psychiatrist, saying that the gun and darts explained why her son had told her that he liked the doctor following his individual interview. When she recognized her feelings, she admitted that she would never allow toys like darts or guns in her house.

Case 6. Another mother, who had had psychotic episodes, used an alligator puppet with large sharp teeth to interact with her three-year-old daughter. Speaking for the alligator, she brought the mouth of the puppet to the child's, saying, "I want to kiss you." Her confusion about love and aggression could not have been better expressed.

Almost all parents welcomed the family interview. They felt, as did the diagnosticians, that it would provide a better picture of the family and the identified patient. Furthermore, they liked the idea of meeting the child psychiatrist with whom they otherwise would have had no contact.

We felt that meeting in the playroom had one more distinct advantage. Most parents have difficulty understanding play interviews and play therapy. The usual interpretation is that they are suspicious or jealous of their child's relationship with the therapist. Nevertheless, in some cases, if not in all, this question is realistic and justified. One cannot think of a better way to acquaint the parents with play interviews than to have them observe and participate in them.

The family's functioning in the diagnostic family interview is the most helpful prelude to family therapy. It can be used effectively in deciding the mode of therapy for the family.

Psychiatric Treatment for Nursing Home Patients: Drug, Alcohol, and Milieu

BY CHING-PIAO CHIEN, M.D., BERNARD A. STOTSKY, M.D., AND JONATHAN O. COLE, M.D.

Following a four-week control period, 64 nursing home patients receiving doxepin, other psychoactive drugs, or no medication were placed on an alcohol regimen of beer or wine in the ward or in a simulated pub setup. The alcohol produced significant improvement in all groups, especially the doxepin group. However, the pub milieu did not demonstrate a significant superiority over ward milieu. The authors suggest that the pub milieu should be used as a catalyzer, rather than as an independent treatment modality, to facilitate the alcohol therapy.

ALCOHOL AS A THERAPEUTIC AGENT for psychiatric patients has received scant attention from researchers and clinicians in spite of the fact that alcohol has been used for thousands of years as both a medicine and a euphoriant. Around the turn of this century, Emil Kraepelin used alcohol, which was christened as "Kraepelin Liquor," in the treatment of mental patients (1). In the last decade only a dozen papers have been published on this subject, even though positive results were reported by several investigators (2–13). Kastenbaum's group (6, 7), for instance, gave wine or beer as a form of tender loving care (TLC) to geriatric patients and observed that they became more sociable, were less incontinent, and required less medication.

One of us (C-p.C.), in a controlled study on a geriatric psychiatric ward, compared the relative efficacy of beer, fruit punch, and fruit punch with thioridazine in a pub milieu, as well as thioridazine on the ward (13). The group receiving beer sociotherapy showed the greatest behavioral improvement, while the drug group ranked second, regardless of the milieu in which the drug was administered. The fruit punch group showed the least improvement despite the fact that it was exposed to a cheerful pub milieu. Thus Chien postulated that the overall efficacy of beer therapy was due to more than TLC alone and was probably a result of the total interaction of the pharmacological property of alcohol and the psychosocial and cultural expectations and experiences associated with drinking beer in a pub-like group setting.

The following questions were raised as a logical consequence of Chien's study. To what extent would beer or wine per se, without the pub milieu, improve the patient? How much does the pub milieu contribute to the beneficial effects of alcohol in geriatric patients? What is the interaction of alcohol and psychotropic drugs? Furthermore, can the pub social therapy, which appeared to be beneficial for the geriatric patient in the mental institution, be applied successfully to elderly persons residing in nursing homes?

Nursing homes have for the most part lacked the resources for providing their patients with active programs of recreation, rehabilitation, and group activities. Since there are over one million patients in nursing homes in this country, the demonstration of a significant therapeutic effect in one or more of these modalities at a reasonable cost could have implications for the treatment of geriatric patients in such institutions.

METHOD

Setting

Two nursing homes with a combined population of 296 patients in the metropolitan area of Boston were selected for the study. These homes were selected because their patients came from a wide range of socioeconomic and ethnic groups and were referred to the homes from a variety of settings.

By law, all the nursing home patients had their own private physicians who were responsible for their medication. These private physicians were general practitioners from the local community. There were well-supervised, well-organized nursing services in the two nursing homes. When this research proposal was presented to the nursing home personnel, discussions were held at various levels, including the administrators, volunteers, occupational therapist, patients, and the general practitioners affiliated with these nursing homes. After thorough consideration the two nursing homes decided to participate in the pub social therapy study.

In one nursing home a former chapel was transformed

Drs. Chien and Cole are with Boston State Hospital, 591 Morton St., Boston, Mass. 02124, where Dr. Chien is Director of Clinical Research and Dr. Cole is Superintendent. Dr. Stotsky is Chairman of the Department of Psychology, Boston State College. The authors are also with the Department of Psychiatry, Tufts University School of Medicine, Boston, Mass., where Dr. Chien is Assistant Clinical Professor, Dr. Stotsky is Assistant Professor, and Dr. Cole is Professor.

This work was supported in part by Public Health Service research grant MH-16128 from the National Institute of Mental Health and by a grant from the United States Brewers Association.

The authors wish to acknowledge the assistance of Mr. W. Haskell and Ms. V. Copeland of the National Health Services, Inc., the physicians and staff of the Martin and Commonwealth Nursing Homes, and Mr. J. Gillis of the C. Pappas Company, who donated the wine for the study.

into a pub ("The Red Hen") with accommodations for 25 people. In the other nursing home a storage room on the first floor was converted into a pub ("The Owl's Nest") that accommodated 30 people. Both these pubs resembled commercial pubs in the community; they had a bar counter, candles, chairs, tables with checkered tablecloths, music, and walls decorated with posters and chianti bottles. The pub setting brought a fresh, exciting atmosphere to the residents that was also appreciated by their visitors.

Subjects

The patients in the nursing home were recruited by their own private physicians and nursing supervisors, using the following criteria:

1. Those who were considered able to remain throughout the study period (eight weeks).
2. Those who had some manifestations of emotional difficulty independent of the existence of a previous psychiatric diagnosis.
3. Those who were willing to participate in a study involving regular ingestion of alcoholic beverages.
4. Those without active manifestation of the following disorders: acute myocardial disease, severe renal or hepatic disease, neurological evidence of cerebrovascular disorder, uncontrolled diabetes, and past or present alcoholism.

Seventy-one patients were finally approved for participation in this study. Of the 71 who started the study 64 were able to participate throughout the entire study period. Seven patients dropped out for various reasons: Five did not consume the alcohol during most of the study because they did not like the type of alcoholic beverage we served, and two dropped out due to unexpected physical illness that was unrelated to the study.

Of the 64 patients, 33 were men and 31 were women, with an average age of 69. The initial plan had been to place all study patients on doxepin or placebo. However, the nursing home physicians were unwilling in many instances to either discontinue a patient's existing psychoactive medication or to have doxepin prescribed for some patients not currently on medication. For these reasons random assignment to drug treatment was not possible. Only the 13 patients (group 1) considered to be pathologically depressed, and for whom antidepressant treatment was judged to be indicated, were therefore placed on doxepin; they are referred to as the doxepin group. Most of the patients in this group had been on tricyclic antidepressants prior to the study period. No psychotropic medication other than doxepin was administered to this group during the study period.

The 30 patients in group 2 had been on various psychotropic medications prior to the study because of various psychiatric problems. The patients' private physicians felt that these medications were optimum both in terms of choice of drug and of dosage. These patients were called the doctors' choice group. They remained on

TABLE 2
Prestudy Scores on GRS, NOSIE, and Zung Self-Rating Depression Scale

Rating	Group 1 Doxepin	Group 2 Doctors' Choice	Group 3 No Medication

their prestudy medications for the whole study period.

Group 3 was composed of the 21 remaining patients, who were considered not to require any psychotropic medication by their private physicians. They had not been on any psychotropic medication for at least six months prior to the study and remained so throughout the study period. They are therefore referred to as the no medication group.

Thus the three groups were preselected according to the judgment of the nursing home medical staff. Our original expectation was that these three groups would differ significantly in psychopathology, but this was not borne out by the baseline evaluation data (see below).

Even though the psychopathological scores for these three groups did not differ significantly, there were some demographic differences between the no medication group and the other two medicated groups.

For instance, the no medication group, which had a mean age of 72.8 years, was significantly older ($p < .05$) than the doxepin and doctors' choice groups (mean ages = 65.4 and 68.6 years, respectively) and was more likely to carry a primary organic diagnosis. More than two-thirds of the no medication group had been referred to the nursing home from a source other than a mental institution, while only one-third of the medicated patients came from such sources (table 1). The doxepin group was similar to the doctors' choice group in terms of demography and past history of medication. One of the initial aims of the study was to compare the clinical efficacy of doxepin with that of various conventional psychotropic drugs administered to the patients in the nursing home.

Treatment Schedules and Ratings

The study lasted eight weeks and was divided into two periods of four weeks each. The first four weeks were considered a control period (nonalcohol period) during which the first group received doxepin in doses of from 25 to 300 mg. per day, the dosage being adjusted for each individual patient by the private physician in consultation with the senior author. The second group continued to receive medication at the doses prescribed by each patient's private physician. The third group received no medication.

The second four weeks (alcohol period) involved the random division of each of the three groups into two subgroups. One subgroup received either a can of beer (12 fluid ounces) or a glass of wine (3 fluid ounces) each afternoon from 1:30 to 2:30 p.m. Monday through Friday *on the ward.* The second subgroup received the same amount of beer or wine *in the pub* at the same time that alcohol was dispensed to the ward drinkers. During the alcohol phase, all three groups remained on the same medication or no medication schedule as had prevailed during the nonalcohol period.

The first ratings were obtained just prior to the initiation of the study. The second ratings were done at the end of the four-week control period (end of nonalcohol period). The third ratings were made at the end of eight weeks (end of alcohol period). All of the ratings were carried out by the same head nurses throughout the study. Raters were trained in the use of rating scales prior to the study, which assured that high reliability existed among the raters.

Instruments Used

The following measures were used:

1. A revised form of the Geriatric Rating Scale (GRS) by Plutchik and associates (14), consisting of 27 items. These items are rated from 0 to 2, and a total score represents the sum of the individual item scores. Higher scores indicate greater behavioral impairment or disturbance.

2. The Nurses' Observation Scale for Inpatient Evaluation (NOSIE). The scores from the NOSIE (15) that were employed for analysis were the total assets score and the scores of factors 1 through 6 (social competence, social interest, personal neatness, irritability, manifest psychosis, and retardation, respectively).

3. A five-point rating scale to measure social activity in the pub and ward settings during the hour when alcohol was served. Ratings ranged from 1, which denotes maximum social participation and group leadership, to 5, which denotes withdrawal from the group and little or no participation. This scale was completed by nursing personnel who actually observed the patients both on the ward and in the pub settings while they were drinking their beverage.

TABLE 4
*Differential Effects of Alcohol Consumption on the Ward Versus in the Pub (Three Groups Combined)**

Rating	Pub	Ward

Factor 6	1.70†	0.74

*Figures were obtained by deducting the third rating scores (end of pub and ward drinking) from the first rating score (prestudy score).
**$p < .10$.
***$p < .05$.
†$p < .025$.

4. The Zung Self-Rating Depression Scale (16). This was not included in the original design but was used in order to investigate whether there were any differences in the depressive features among the three groups. This self-rating scale was used only for the initial rating and not for the subsequent ratings because of difficulty in gaining patient cooperation.

A record was kept of any adverse reactions or unusual behavior that occurred during the course of the eight weeks. Since this was an open study, the senior investigator would investigate each report by examining the patient and discussing the findings with the staff.

The data were analyzed at the Harvard University Computer Center using an analysis of variance technique based on difference scores, or t test where appropriate.

RESULTS

Pretreatment Measures

Despite the fact that the patients in the three treatment groups were selected nonrandomly on the basis of their past medication, history, and availability for inclusion in a doxepin group, they showed no significant differences in any of the eight major criterion measures on the GRS and NOSIE. Although the doxepin group had presumably been selected because of a preexisting depression, analysis of variance on the scores on the Zung Self-Rating Depression Scale showed that all three groups averaged a mild level of depression (equivalent to "depressed-outpatient" level), with the doxepin group falling in an intermediate level between the two other groups (see table 2).

Results at the End of the Four-Week Baseline Period

During the first four weeks of the study the doxepin group received increasing doses of this antidepressant drug. The other two groups stayed on their previous treatment regimen. The doxepin group showed no significant changes during this first period. The doctors' choice group showed a significant deterioration in the GRS scores and a trend toward improvement on the irritability and retardation factors of the NOSIE. The no medication group showed significant improvement on the social competence and retardation factors of the NOSIE (see table 3).

Changes During the Alcohol Treatment Period

After four weeks of exposure to beverage alcohol in either the ward or the pub setting, a somewhat larger number of significant differences were observed, comparing the scores on the criterion measures at eight weeks with those at the pretreatment period (see table 3). There was a general increase on the total asset score on the NOSIE, ranging from a trend toward improvement in the no medication group to a significant improvement in the other two treatment groups. Of the eight criterion measures used, five showed significant change or a trend toward significant change in each of the treatment groups. Although almost all changes observed were in the direction of improvement and almost all significant changes were in the direction of improvement, differences between the three treatment groups were not striking. The doxepin group did, however, show more improvement on the GRS score and on the total asset score of the NOSIE as well as on five of the six NOSIE factors.

As can be seen from table 3, the magnitude of the change during this second four-week period, during which beverage alcohol was administered once a day, was relatively larger than the change during the initial baseline period. Statistical significance of the superiority of the alcohol period to the nonalcohol period was examined by the paired t test, which compared the changes obtained in the nonalcohol period to those of the alcohol period. Again, significance or trend toward significance, almost all in favor of the alcohol period, was noted in four to six of the eight criteria measured in each of the three groups, with the doxepin group ranking highest in improvement.[1]

Differential Effects of Alcohol Consumption on Ward Versus Pub

The effects of alcohol therapy administered in two different milieus were compared between ward drinkers and pub drinkers with three groups combined. On the eight major criterion measures used, the patients consuming alcohol in the pub setting showed more improvement than the patients receiving it on the ward on all measures but the NOSIE factors of irritability and personal neatness. Significantly greater change favoring the pub setting, however, was observed only on the NOSIE factors for social competence, manifest psychosis, and retardation (table 4).

When changes within the doxepin, doctors' choice, and no medication groups are examined, contrasting re-

[1]Copies of a table giving detailed data are available from the authors on request.

TABLE 5
Patients' Subjective Assessment of the Pub Sociotherapy, in Percentages

Question	Yes	No	Uncertain
Did you enjoy the pub?	86.8	13.2	0
Do you think the pub social meeting helped you?	80.3	19.7	0
Would you like to see this program continue?	88.5	8.2	3.3

sponses between those patients in each group receiving an alcoholic beverage in the pub with those receiving it on the ward, a similar pattern is obtained. Again, the magnitude of improvement is generally slightly to somewhat greater in the pub setting than in the ward setting. This trend is least evident in the doxepin group.

Out of 24 tests of significance comparing change in the pub drinking with change in the ward drinking within each medication group, only two statistically significant differences were found. The no medication group improved significantly more in manifest psychosis in the pub setting, while the doctors' choice group improved significantly more in retardation in the pub setting. There was a trend ($p < .10$) in favor of the pub setting for the doctors' choice group in total assets on the NOSIE and for the doxepin group in social competence.[2]

Activity Score in the Pub and on the Ward

A comparison of the pub and ward drinkers for social activity scores during the drinking hours revealed more activity in the pub (mean average = 2.8) than on the ward (mean average = 3.3). This difference was significant ($p < .005$). Obviously, the pub had social facilitation value during the drinking hours.

Patients' Assessment of the Pub

The patients receiving the alcoholic beverage in the pub setting were asked whether they enjoyed the pub, whether they thought the pub social meeting helped them, and whether they would like to see the program continue. As noted in table 5, over 80 percent of the group responded positively to each of the three questions. Since the questionnaire was administered primarily to aid the nursing home administrators in deciding whether permanent pubs should be set up when the study ended, information on the patients' attitude toward ward drinking was not obtained.

Analysis of types of drinks preferred revealed that more than half of the population (59.4 percent) ordered beer, with proportionately more men preferring this beverage. A total of 26.6 percent preferred wine and 14 percent were equally satisfied with both. It should be noted that the study was carried on in the summertime and that there were only two kinds of drinks—beer and wine—served for the purposes of the study.

[2] Copies of a table giving detailed data are available from the authors on request.

DISCUSSION

The major aim of the study was to evaluate the contribution of the pub social milieu to the benefits of receiving a drink of beer or wine among geriatric patients in a nursing home. As shown in our findings, the pub drinking was liked by the majority of the patients and facilitated more social interactions during a short period, but did not demonstrate a strikingly significant superiority over ward drinking on the NOSIE and GRS. The beneficial value of pub milieu in the alcohol therapy is limited as far as sustaining effects on behavioral change are concerned. This finding is somewhat similar to that of Greenblatt (17) and May (18), who demonstrated that milieu therapy provided little impact on schizophrenic patients when it was compared to drug therapy. Thus the pub social milieu could be used as a catalyzer, rather than as an independent treatment modality, to facilitate the alcohol therapy.

Within the larger study population, a group of 13 patients had been selected by their private physicians and the nursing home staff to receive doxepin, a new antidepressant drug. Although this group did not appear either more depressed on Zung's depression scale or more impaired on the GRS or on the NOSIE ward behavior scale than did the other two groups of patients studied, they did in fact show somewhat more improvement on the criterion measures during the second four weeks of the study. They also showed slightly less difference in relative response to the pub or the ward setting than did the other two groups. The clinical change observed in this group can be considered to favor the premise that doxepin may be of some value in patients of this sort, particularly when it is combined with a euphoriant such as alcohol. More vigorous claims for the therapeutic efficacy of doxepin cannot be made on the basis of the present study since patients were not randomly assigned to doxepin or other treatments, and the doxepin group may well have differed from the other treatment groups in ways not accounted for by the measures recorded during the study.

In an earlier study involving predominantly Irish patients, one of us (C-p.C.) demonstrated the efficacy of alcohol in a pub setting on the chronic geriatric wards of a public mental hospital (13). The present study extends this work to a nursing home with various subcultural populations and again provides evidence supporting the value of this ancient and culturally valued drug in the treatment of geriatric patients in nursing homes as well.

SUMMARY AND CONCLUSIONS

Sixty-four nursing home patients were studied for eight weeks—a four-week nonalcohol period and a subsequent four-week alcohol period. They were allocated to three treatment groups: a doxepin group, a doctors' choice group whose members received various psy-

chotropic medications considered to be optimal by their private physicians, and a no medication group. Although these three groups were preselected by their physicians for their treatments and one might assume that they would differ from each other, objective rating scale data (GRS, NOSIE, and Zung's Self-Rating Depression Scale) did not show any difference among the three groups in terms of psychopathology.

In the first four weeks, the nonalcohol period, all three groups failed to show significant improvement. The doctors' choice group deteriorated significantly on the GRS.

In the subsequent four weeks, the alcohol period, all groups received beer or wine once daily in addition to the previous treatment condition; half of each group, by random division, was served in the nursing home pub and the other half in the ward setting.

Regardless of the setting, the introduction of alcohol was associated with significant improvement in all groups in various aspects of the rating scales. Both ward and pub subjects showed significant improvement. Comparison of the pub versus ward drinking revealed that pub drinking was better than ward drinking in only four of 24 sets of comparisons. Thus the beneficial value of the pub milieu in alcohol therapy was limited, at least when its long-acting effect was examined. During the alcohol period, the doxepin group had a trend toward greater improvement than the other two groups.

There were no serious side effects noted with combination of drug and alcohol at the dosage prescribed. The attendance rate at the pub was 85.5 percent, an unusually high popularity for any psychiatric treatment available for this aged group. Thus pub milieu should be used as a catalyzer, rather than as an independent treatment modality, to facilitate the alcohol therapy.

The Effect of Interview Language on the Evaluation of Psychopathology in Spanish-American Schizophrenic Patients

BY LUIS R. MARCOS, M.D., MURRAY ALPERT, PH.D., LEONEL URCUYO, M.D., AND MARTIN KESSELMAN, M.D.

Psychiatric ratings of ten schizophrenic patients whose native language was Spanish disclosed more psychopathology when the patients were interviewed in the English language than when they were interviewed in Spanish. Some evidence suggested that there were clinically important changes in the patient attributable to his problems in speaking in a second language. The clinician's frame of reference must also be taken into account: what is applicable to native English-speaking patients cannot be directly applied to the evaluation of persons from other cultures.

AT BELLEVUE PSYCHIATRIC HOSPITAL, as in many other urban centers, Spanish-speaking patients comprise a significant proportion of the patient population (1, 2) while Spanish-speaking psychiatrists are uncommon. As in many psychiatric facilities, it is a frequent practice to have patients whose mother tongue is not English evaluated by psychiatrists who speak only English. If the patient is able to communicate at all in English the examination is done in this language. Only if the patient is entirely non-English-speaking might an interpreter be used. Our purpose in the research reported here is to assess the influence of interview language on the psychiatric evaluation of schizophrenic patients whose native tongue is Spanish.

A number of authors (3–7) have pointed out the need for mental health professionals who possess both fluency in Spanish and a sensitive understanding of the Spanish-American culture. It is difficult to measure the sensitivity of a clinician to an unfamiliar culture, and it is not surprising that there has been little direct experimental work studying this issue. However, the sheer ability to speak a language is less elusive to measurement and, considering the emphasis on communication dysfunction in some theories of psychopathology, it is surprising that the role of interview language in the assessment of pathology in bilingual patients has received very little experimental attention.

We could find only one report on this topic. In this report, Del Castillo (8) described several clinical experiences in which Spanish-speaking patients appeared obviously psychotic during native-tongue interviews but seemed much less so, and even without any overt psychotic symptoms, when the interview was conducted in English. In this latter report, the interviews were part of pretrial examinations. The interviewer was free to conduct the interview in any manner he chose in order to accomplish this goal. Under these circumstances it is difficult to evaluate the extent to which the interview procedure apart from the interview language, contributed to the difference in detected pathology. Moreover, the issue of legal competence is a somewhat circumscribed one and may reflect only certain components of the psychiatric evaluation.

We have recently developed a method for obtaining standardized psychiatric mental status evaluations utilizing a combination of prerecorded interview questions and closed-circuit television. This procedure has been described in detail elsewhere (9, 10). In effect, it provides a reliable method for minimizing interview variability and for attaining a permanent record that may be rated under well-controlled conditions. The method has been shown to be at least as sensitive as the standard face-to-face procedure in the assessment of level of psychopathology and in the estimation of response to treatment. Utilizing this method we undertook a study of the effect of interview language on the rating of psychopathology. It was our expectation that by separating the rater from the interview situation we would be able to derive a clearer understanding of this effect.

METHOD

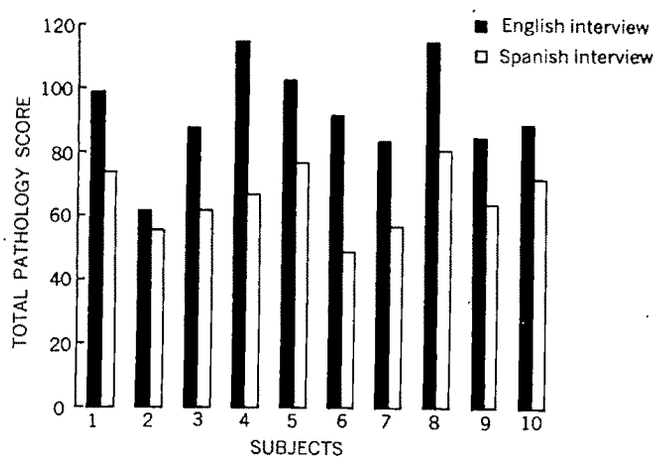
Ten recent admissions to the adult services of Bellevue Psychiatric Hospital were selected for this study. The criteria for admission to the study were as follows: 1) diagnosis of schizophrenia, made independently by two psychiatrists; 2) no evidence of organic brain disorder; 3) Spanish as the native language; 4) fluency in English sufficient to participate in English psychiatric interviews; and 5) willingness to volunteer for the study. Patients were not informed as to the aim of the study. In table 1

Dr. Marcos is Clinical Instructor and Postdoctoral Fellow, Department of Psychiatry, Downstate Medical Center, State University of New York, 450 Clarkson Ave., Box 88, Brooklyn, N.Y. 11203. Drs. Alpert, Urcuyo, and Kesselman are all associated with the New York University Medical School Department of Psychiatry, where Dr. Alpert is Associate Professor of Psychiatry, Dr. Urcuyo is Staff Psychiatrist, and Dr. Kesselman is Assistant Professor of Psychiatry.

This study was supported in part by Public Health Service grant MH-08618 from the National Institute of Mental Health.

The authors wish to express their appreciation to Paul Beatty, Florence Diamond, Victor Martin, Sanghae Park, and Nelly Pastoriza.

TABLE 1
Description of the Patient Sample



Subject	Sex	Age	Years of Education	Years in United States	Wechsler Vocabulary Score		Diagnosis	Drug Treatment
					English	Spanish		
1	M	21	9	3	10	20	Chronic undifferentiated schizophrenia	300 mg. chlorpromazine
2	F	34	9	24	27	38	Chronic undifferentiated schizophrenia	400 mg. chlorpromazine
3	M	32	10	20	36	38	Faranoid schizophrenia	200 mg. chlorpromazine
4	F	31	12	25	35	49	Paranoid schizophrenia	400 mg. chlorpromazine
5	M	34	11	17	23	42	Chronic undifferentiated schizophrenia	30 mg. trifluoperazine
6	M	31	9	10	56	68	Paranoid schizophrenia	20 mg. trifluoperazine
7	F	34	5	18	9	28	Chronic undifferentiated schizophrenia	300 mg. chlorpromazine

9	M	21	9	20	60	34	Paranoid schizophrenia	350 mg. chlorpromazine
10	M	42	7	39	50	18	Chronic undifferentiated schizophrenia	30 mg. trifluoperazine

the background and clinical characteristics of the patients are listed.

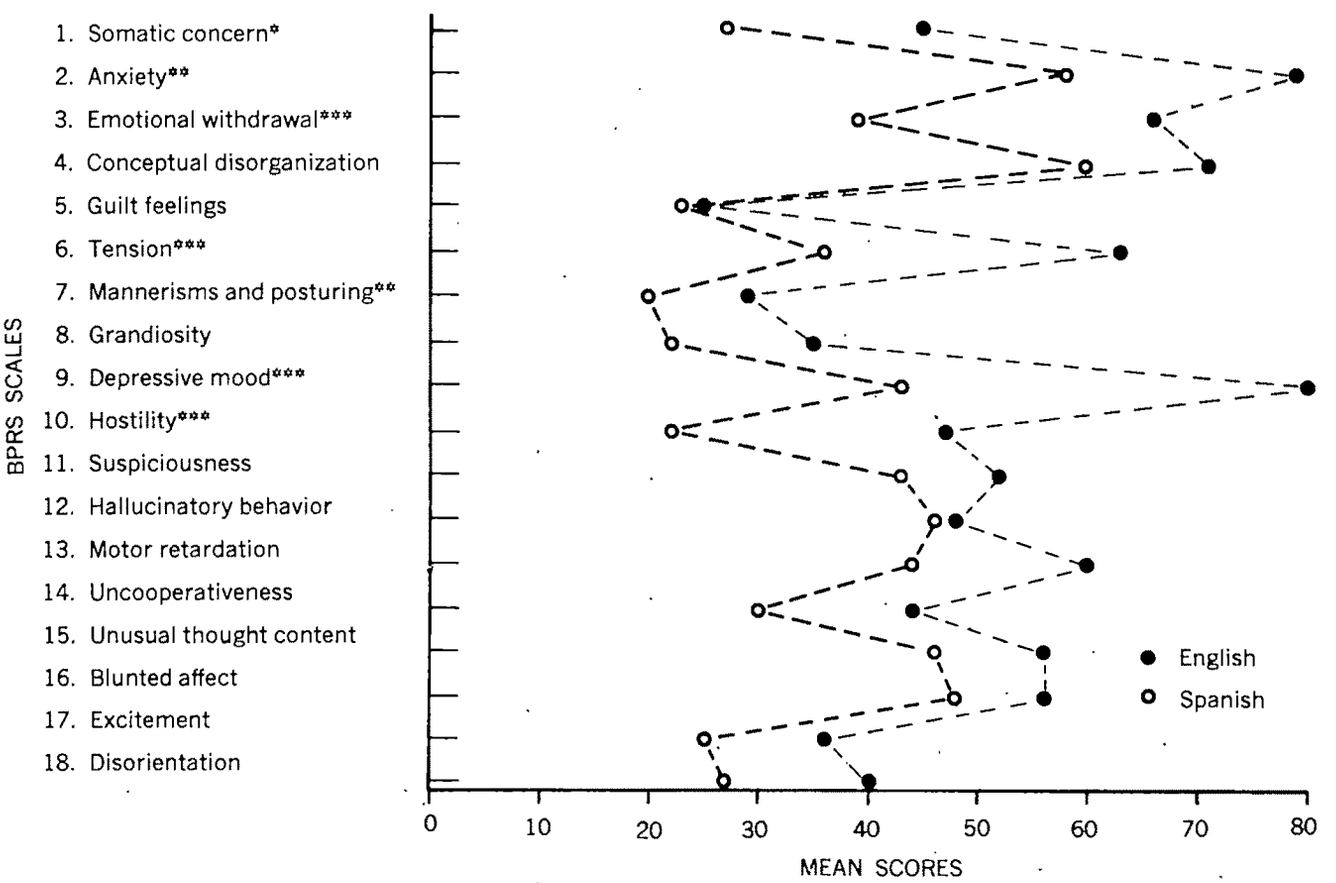
Four psychiatrists contributed independent ratings of the videotapes. Two had Spanish as their mother tongue and two were English-speaking. The four psychiatrists were experienced in the use of the Brief Psychiatric Rating Scale (BPRS) (11) and had previously participated in training sessions designed to establish acceptable levels of interrater reliability. Raters were blind as to the purpose of the study and to the admission criteria as well.

In order to study the interrater reliability between English- and Spanish-speaking raters, one of the English and one of the Spanish raters viewed ten additional videotape interviews of English-speaking schizophrenic patients. Interrater reliability for these ratings, based on the total pathology scores, was $r = .85$ ($t = 4.56$, $p < .01$). The means of the total pathology scores were 50 for the English-speaking rater and 49 for the Spanish-speaking rater. These mean scores were not statistically different ($t = 1.04$, $df = 9$, $p > .3$).

FIGURE 1
Total BPRS Pathology Scores for Each Subject in English and Spanish Interviews

Closed-circuit television recordings were made of standard psychiatric interviews in English and Spanish. Half of the patients participated in the English interview first and vice versa. The two interviews were spaced no more than 24 hours and no less than 20 hours apart. During this period no change was made in the patient's medication. An English-speaking or Spanish-speaking clinician was present during the interview; however, his participation was minimal since the interview questions had been put on audiotape. The English and Spanish questions, which were identical, were presented in the same order. The videotape recordings of the English-language interviews were independently rated by the two English-speaking psychiatrists; the interviews in Spanish were also rated independently by the two Spanish-speaking psychiatrists. Finally, both the English and the Spanish versions of the vocabulary subtest of the Wechsler Adult Intelligence Scale (12) were administered to the patients after the psychiatric interviews had been completed.

RESULTS



To determine whether the language of the interview would have an effect on the amount of pathology detected by the raters, we computed the total pathology score for each patient. This score, which is the sum of the ratings on the 18 BPRS scales for the two raters per language, is presented for each patient in figure 1. In this figure it can be seen that more pathology was detected during the English interview for each patient. The mean score for the English-language interviews was 93 and for the Spanish-language interviews 65; the difference was highly significant statistically ($t = 7.11$, $p < .001$). Interrater reliability for the Spanish-speaking raters was .91 ($t = 6.31$, $p < .001$). The difference between the mean levels of pathology detected by the two Spanish raters was not statistically significant. Interrater reliability for the English-speaking raters was also .91. The means of the total pathology scores were 48 for English-speaking rater

1 and 45 for English-speaking rater 2. The difference between these means, although small from a clinical point of view, was statistically significant ($t = 2.61$, $p < .05$). However, this difference between the English-speaking raters would not contribute to the difference between the English and Spanish ratings. It was English-speaking rater 1 who, together with Spanish-speaking rater 1, participated in the preliminary reliability study in which it was found that English-speaking rater 1 and Spanish-speaking rater 1 detected equivalent levels of pathology. Since English-speaking rater 2 tended to rate lower than English-speaking rater 1, this would if anything tend to decrease the levels of pathology detected on the combined English ratings.

From this analysis it is clear that our bilingual patients have been judged to demonstrate more pathology when they have been interviewed in English. To determine whether this increment in pathology in the English-language interviews reflected a simple constant added to the amount of pathology detected in the Spanish-language interviews, the product-moment correlation between the total pathology scores in English and Spanish was computed, and was found to equal .64. This correlation was significantly different from zero but was lower than the correlation we usually obtain when two of our experienced raters evaluate the identical behavioral sample. (The five-percent confidence limits for a correlation of .64 with an N of 10 are .36 and .81.) The lowering of interrater correlation across languages might be interpreted as suggesting that patients are differentially affected by the language of the interview.

We will now report the effect of the language of interview on the individual BPRS scales. In figure 2 the mean score for each scale is presented for both the English and Spanish interview. The mean scores are significantly elevated for seven of the 18 scales (t test between correlated means). The scales most affected by the language of the interview were "tension," "depressed mood," "hostility," "anxiety," "emotional withdrawal," and "somatic concern."

FIGURE 2
Pathology Score for Each BPRS Scale in English and Spanish Interviews

**p<.05.
***p<.01.

The differences between the English and Spanish interviews for the rest of the scales were not statistically significant.

DISCUSSION

Our results indicate that Spanish-American patients are consistently rated as showing more pathology when they are interviewed in English. Even the two patients who obtained higher vocabulary scores in English than in Spanish were evaluated as presenting more pathology in their English-language interview. The vocabulary score is not a direct measure of language fluency, but this finding would suggest that caution should be taken in the psychiatric evaluation of patients whose first language is not English, including those who appear competent in it.

Our results disagree with those of Del Castillo (8), who conducted interviews in both Spanish and English and felt that he uncovered more pathology in Spanish interviews with Spanish-American patients. A factor that might have contributed to the discrepancy could be related to the different effects of pathology in the two studies. In Del Castillo's setting it was to the advantage of the patients to demonstrate enough pathology to avoid trial. Our patients frequently want to minimize their symptoms in order to elude long-term hospitalization. Patients who are more competent in Spanish may be better able to communicate the level of pathology that will produce the most desirable disposition for them. However, it is unlikely that the amount of pathology detected in a psychiatric examination is simply a function of the impression the patient wishes to make.

There are three general factors that should be considered here—one related to the raters, one related to the patients, and one residing in the interaction between the raters and the patients. First, we might hypothesize that patients are actually the same in the English and the Spanish interviews. The average patient received a total pathology score of 46.5 for his English interview and 32.5 for his Spanish interview. The higher pathology scores given by the English-speaking raters or the lower scores given by the Spanish-speaking raters could reflect rater prejudice. Brody (13) has mentioned the possibility of positive as well as negative prejudice; he has attributed the roots of prejudice to intrapsychic factors within the prejudiced individual.

Whether the ratings of the English or the Spanish interview are taken as reflecting the "true" pathology, the 14-point difference between the ratings can be seen as representing the mean of a distribution of prejudice points and could be viewed as separable from the distribution of pathology points. If this were so it would be difficult to explain the high interrater correlation between the two English-speaking and the two Spanish-speaking raters (for both, $r = .91$), since if prejudice points were attributes they might be expected to be distributed more randomly across the patients and would thus dilute the correlation. Of course, pairs of raters might share identical stereotypes; we cannot eliminate such a possibility with these data.

To further check on the prejudice hypothesis, a multiple correlation was computed between the English Pathology Score, the Spanish Pathology Score, and the Spanish Vocabulary Score. The reason for looking at these independent predictors was that they were patient variables unavailable to the English-language rater. The multiple correlation was .83, and each of the predictors independently added significantly to the correlation analysis of variance (ANOVA). It is hard to imagine any simple prejudice mechanism through which these orderly relations could operate from predictors not accessible to the rater.

Although we can account for a significant part of the difference between the English and Spanish ratings in terms of patient variables, we cannot exclude the possibility that both positive and negative rater prejudices contributed to the different levels of pathology found.

The second factor that might operate to produce the increment in English interview pathology is related to the hypothesis that the patient changes when he is required to speak English. Under the best of circumstances, schizophrenics find it difficult to describe their experiences. They may be tense when speaking in English (scale 6). They may just "give up" in their attempt to communicate and appear more emotionally withdrawn (scale 3) and uncooperative (scale 14). We have some evidence that this factor was operative; we will report differences between the patient's responses to identical questions in Spanish and English in a separate report (14).

The third factor derives from the fact that the raters' frame of reference is not applicable to the special problems of the Spanish-American patient. For example, in a previous study we showed that when an English-speaking patient becomes depressed, a number of things change in the way he speaks; these include an increased duration of articulations and markedly increased pause times (15). Some of these changes may also be found when an individual speaks in a language in which he is less competent, so that the rater might confuse the effects of translation with the effects of depression (scale 9). Similarly, Mahl (16) has demonstrated that speech disturbances are verbal indicators of anxiety. We have found more of the speech disturbances that Mahl has described in our patients while they speak English and thus would expect elevation in the anxiety ratings (scale 2).

In addition, under this factor the problems of norms for cross-cultural ratings might be subsumed. For example, Fernandez-Marina (17) has described the "Puerto Rican syndrome," emphasizing the conversion reaction component. Fabrega and associates (18) and Wolf (19) have noted an increased frequency of somatic complaints in Mexican-American and Puerto Rican patients. Thus one might expect an elevation on scale 1 ("somatic concern"). Spanish-speaking raters appear to have a more culturally relative attitude and seem better able to evaluate these patients' statements within the context of their Spanish-American cultural background.

CONCLUSIONS

In a study of ten schizophrenic patients whose mother tongue was Spanish we found that psychiatric ratings reflected greater psychopathology when the patients were interviewed in English than when they were interviewed in Spanish. Although a contribution from rater prejudice (both positive and negative) could not be excluded, there was evidence suggesting clinically relevant changes in the patient attributable to the problems of speaking in a second language. There were also indications that the clinician's frame of reference, which is applicable to native English-speaking patients, cannot be directly applied to the evaluation of patient behaviors that are influenced not only by psychopathology but by cross-cultural, cross-language factors as well.

Because of the limited number of trained professionals who are competent in Spanish, we expect the practice of interviewing patients in their less competent language to continue. We are currently in the process of analyzing the verbal and nonverbal communication differences from our closed-circuit television recordings to ascertain the nature of the differences. We are also trying to determine whether we can provide the English rater with a yardstick to minimize some of the constant errors resulting from the interview language.

A Unified System of Care: Blueprint for the Future

BY ALLAN BEIGEL, M.D., WILLIS H. BOWER, M.D., AND ALAN J. LEVENSON, M.D.

The authors describe the means used in Pima County, Arizona, to unify and coordinate the policies and procedures of a state hospital system and a community mental health system in order to provide more effective delivery of mental health services at the community level. The cooperation of the state hospital also permitted the development of a deterrent to unnecessary state hospitalization and a reduction in the number of patients to a level at which more specific therapeutic programs could be developed to meet the needs of the patients who remained.

SINCE THE INCEPTION of the community mental health center program in 1963, many states have been supporting two systems of mental health service delivery—a state hospital system that has been in existence for many years and a recently developed community mental health center system. Even though the large majority of states have unified these two systems administratively into a single state department of mental health, the actual delivery of services continues to be competitive rather than cooperative.

The new system, the community mental health center, is often viewed as a threat by the old system, the state hospital. Proponents of the new system, on the other hand, often see the old system as obsolete and unnecessary. Whatever the merits of the arguments between proponents of each system, it is clear that a conflict between mental health systems can be easily created, and this often has a negative effect upon funding sources. For example, if legislators see mental health professionals as being unable to agree, they may provide less funding, thereby decreasing the effectiveness of both systems of care.

At the same time, federal, state, and local funding resources are placing increasing emphasis on data that will demonstrate the social benefit, cost effectiveness, and efficiency of new services. Numerous allegations have been made concerning the cost effectiveness of new therapeutic modalities that are a part of community mental health center services, such as walk-in clinics and day programs, but demonstrations of their actual impact on cost effectiveness have been infrequent.

Recently, in New York City, it has been required that the progress of mental patients must be demonstrated by facilities in order to assure continued public support of services. In announcing the mailing of a "change in client condition report," Dr. Herbert Fill, Commissioner of the New York City Department of Mental Health and Retardation Services, observed, "We consider such data of extreme significance when related to social benefit, costs, and the ability to show tangible outcome of city, state, and federal funding sources" (1).

If mental health is to continue to enjoy its relatively favorable position of recent years, not only will such data have to be provided, but conflict will also have to decrease between these separate systems of care and communities and states will have to move toward a single system of mental health delivery. State hospital systems and community mental health systems will have to be encouraged to develop program ties that can be analyzed as to their cost effectiveness (2, 3).

This paper will describe a relationship between community mental health services in Pima County (Tucson), Arizona, and state hospital services located in Maricopa County (Phoenix). Through this program, a unified and coordinated direction, policy, and procedure have been given to the delivery of mental health services within Pima County, resulting in the more effective delivery of increased services at the community level. The model and mechanisms used to effect these ties can serve as a blueprint for the future for other communities and states that are currently experiencing this continued competition between two systems of care.

A BRIEF HISTORY

Prior to September 1970 in Pima County, Arizona, there were three noncoordinated methods of providing mental health care to those who could not purchase private treatment. The Pima County Hospital, operated by the county health department, was charged by law with the immediate care and detention of individuals who possibly required mental health care. Admission to the Pima County Hospital was by a petition for commitment only, and treatment rarely extended beyond the use of drugs. Psychiatric evaluations were completed and a court hearing was held that resulted in the commitment of the patient to the Arizona State Hospital for further treatment or a discharge without coordinated follow-up.

The Arizona State Hospital in Phoenix received com-

Drs. Beigel and Levenson are with the Department of Psychiatry, University of Arizona College of Medicine, Tucson, Ariz., where Dr. Beigel is Assistant Professor and Dr. Levenson is Professor and Head; Dr. Beigel is also Director, Southern Arizona Mental Health Center, 1930 E. Sixth St., Tucson, Ariz. 85719, and Chief of Psychiatry, Pima County Hospital, Tucson. Dr. Bower is Director, Arizona State Hospital, Phoenix, Ariz.

mitted patients from Pima County. Although a unit system, based upon geographic relationships, had been organized in 1967, continuity of care and the coordination of services with those located in Pima County were minimal.

The Southern Arizona Mental Health Center in Tucson, an outpatient branch of the Arizona State Hospital, was established in 1962. Created initially to function as a follow-up clinic for patients discharged from the Arizona State Hospital, it broadened its approach over the years by developing more programs that reached out to the community. Nevertheless, because the Southern Arizona Mental Health Center did not have an inpatient facility and because the responsibility for commitment belonged to the Pima County Hospital, the center was totally unable to make an impact on the rates of hospitalization and rehospitalization at the Arizona State Hospital.

In late 1968, a task force was formed by the Pima County Health Department, including representatives from the center, the state hospital, and the department of psychiatry at the newly formed University of Arizona College of Medicine. From these discussions, which lasted 18 months, a tightly organized agreement was signed that resulted in the pooling of resources and the placing of services within a unified service network. This Combined Mental Health Care Program was designed to provide community-based crisis intervention and brief hospitalization, with the express purpose of decreasing the need for hospitalization at the Arizona State Hospital and of maximizing the cost effectiveness of the mental health dollars being spent.

It is now headed by a coordinator, who also functions as chief of psychiatry at the Pima County Hospital and as director of the Southern Arizona Mental Health Center. A conference committee, consisting of representatives from the Pima County Health Department, the Arizona State Hospital, and the University of Arizona, acts as an advisory and policy-making body. A citizens advisory board also provides guidance.

EFFECTS ON SERVICE DELIVERY

The Combined Mental Health Care Program was initiated on September 1, 1970. Data have been gathered over a 16-month period, ending December 31, 1971, and have been compared with the 12-month period prior to the initiation of the program.

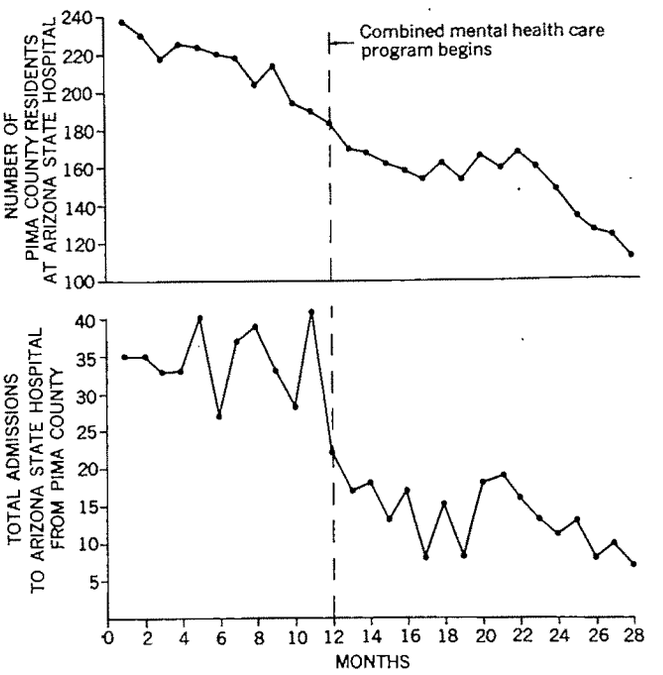
As can be seen from figure 1, the Combined Mental Health Care Program has had a dramatic effect on the rate of admissions to the Arizona State Hospital from Pima County. From an average of 33.6 admissions per month during the 12 months prior to the initiation of the Program, a decrease to 13.2 has been noted during the next 16 months. Furthermore, the rate of civil commitments to the Arizona State Hospital from Pima County has also markedly decreased, from 75 percent of all admissions to the Arizona State Hospital from Pima County (September 1969–August 1970) to only 39 percent since the program began.

The initiation of the Combined Mental Health Care Program has also had an effect on the Pima County census at the Arizona State Hospital (figure 1). The sharp decrease in admissions to the Arizona State Hospital from Pima County has led to a decrease in the number of residents of Pima County at the Arizona State Hospital. Furthermore, because of this continuing decrease in the census of Pima County patients at the Arizona State Hospital, the hospital has been able to develop more specialized programs, such as for chronic institutionalized patients, that will better meet the needs of those who remain at the Arizona State Hospital.

These achievements are a direct result of the coordination of services between the Southern Arizona Mental Health Center and the Pima County Hospital. The availability of a walk-in clinic at both the Southern Arizona Mental Health Center and the Pima County Hospital, offering immediately available and accessible crisis intervention services 24 hours a day, seven days a week, on a face-to-face basis with a mental health professional, has helped to decrease the number of admissions to the Pima County Hospital (figure 2).

Furthermore, prior to the initiation of the program, all patients admitted to the Pima County Hospital Neuropsychiatric Unit entered on a court-issued detention order. Involuntary hospitalization introduced legal procedures into the hospital setting that often deterred the staff from the initiation of active treatment. With the change in orientation of the inpatient services to voluntary, short-term crisis intervention, 75 percent of all patients now enter voluntarily.

FIGURE 1
Pima County Residents at Arizona State Hospital: Number and Rate of Admissions (September 1969–December 1971)



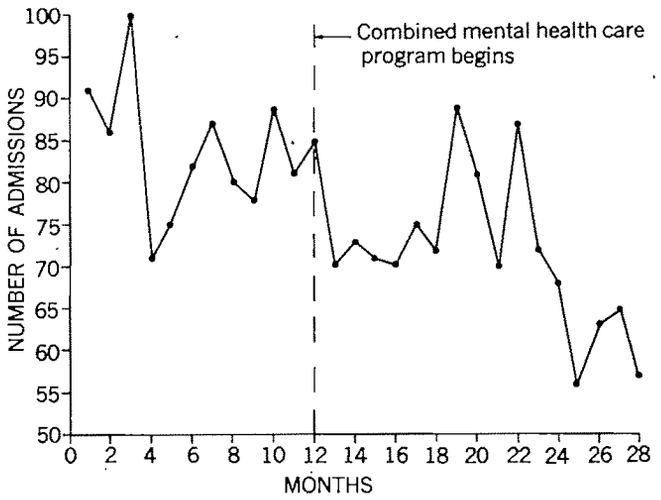


FIGURE 2
Psychiatric Admissions to Pima County Hospital (September 1969–December 1971)

Another result of the decrease in admissions to the Pima County Hospital due to the crisis intervention efforts of the walk-in clinic has been a decline in the average daily census of the inpatient unit from 16.8 (on a 20-bed unit) prior to the initiation of the program to an average of 13.0 during the last four months of 1971. This decrease in average daily census, however, has not been accompanied by a decrease in the average length of stay (6.8 days). Consequently, with fewer patients being admitted, the staff of the inpatient unit is able to provide more intensive treatment services than was possible prior to the initiation of the Combined Mental Health Care Program.

Within the framework of the Combined Mental Health Care Program, another relationship between the Pima County Hospital and the Southern Arizona Mental Health Center has been developed. Patients who enter the Pima County Hospital voluntarily can be transported each day from the Pima County Hospital to the Southern Arizona Mental Health Center day program for milieu treatment if it is indicated. These patients often continue in the day program following their discharge from the hospital. The availability of this relationship has enabled the staff at the Pima County Hospital, with its limited facilities, to expand the number of treatment modalities that are available to patients who are admitted.

Another outgrowth of the Combined Mental Health Care Program has been its effect on geriatric patients. Previously, many of them were sent to the Arizona State Hospital on a commitment basis when available nursing home facilities within the community would not accept them for care. Through the Combined Mental Health Care Program, psychiatric consultation has been made available to the county nursing home. Consequently, it has been more willing to accept geriatric patients who were being inappropriately sent to the Arizona State Hospital. During the past six months, all geriatric patients who have been evaluated as suitable for nursing home care rather than state hospital care have been transferred back to Pima County from Arizona State Hospital and into appropriate nursing home programs. Over 60 percent of all geriatric patients at the Arizona State Hospital from Pima County were found suitable for such transfers.

THE "FAIR SHARE" PLAN

In creating the Southern Arizona Mental Health Center in 1962, the Arizona State Hospital had hoped to justify the additional expenditure for staff and personnel in Tucson by decreasing the rate of hospitalization from Pima County. This decrease had not occurred. The creation of the Combined Mental Health Care Program was also intended to produce fiscal results that would justify the continued existence and expansion of the Southern Arizona Mental Health Center.

Therefore, a method for performing a cost analysis was worked out based on a "fair share" of the Arizona State Hospital budget for Pima County, computed on the basis of population, with Pima County being entitled to 20.3 percent since this is the percentage of people in the state residing within Pima County.

Tables 1–3 illustrate the impact of the Combined Mental Health Care Program on the expenditures for the care of patients from Pima County at the Southern Arizona Mental Health Center and the Arizona State Hospital. Prior to the initiation of the Combined Mental Health Care Program, as noted in table 1, the program for Pima County residents at the Southern Arizona Mental Health Center and the Arizona State Hospital were operating at

TABLE 1
Cost Analysis and "Fair Share" Calculation for Pima County Residents: June 1970

Treatment Modality	Daily Charge per Patient (June 1970)	Pima County Census at Arizona State Hospital (ASH)	Total Daily Cost
Adult psychiatry	$15.46	132	$2,043.72

Early discharge	30.59	1	30.59
"Flamenco II" program	16.54	10	165.40
Total		160	$3,084.79
			x 365
Annual cost of Pima County residents at ASH			$1,125,948
Southern Arizona Mental Health Center budget			+ 637,582
Total expenditures for Pima County			$1,763,530
Pima County "fair share" of total ASH 1970–71 budget*			- 1,737,802
"Deficit" from "fair share"			$ 25,728

*20.3 percent of $8,560,605.

an "annual deficit" from the "fair share" of $440,952. In other words, the combined cost of caring for patients from Pima County at the Arizona State Hospital and the Southern Arizona Mental Health Center was $440,952 more than the amount allotted for Pima County ($1,406,342) as determined through a computation of the "fair share" of the total Arizona State Hospital budget.

By March 1971, six months after the initiation of the Combined Mental Health Care Program, this "deficit" had been reduced to $25,728 (table 2). By December 1971, 16 months after the initiation of the Combined Mental Health Care Program, a "surplus" of $108,534 (table 3) had been generated. It has been jointly agreed that any surplus in the "fair share" will be translated into additional positions for the Southern Arizona Mental Health Center, to be utilized to deliver locally based community services. Conversely, any deficit will be taken out of the budget of the Southern Arizona Mental Health Center, to be used for the care of patients from Pima County at the Arizona State Hospital.

The surplus that has been accumulated to date has enabled the Southern Arizona Mental Health Center to expand its community-based programs. The Southern Arizona Mental Health Center and the Arizona State Hospital were able to approach the legislature with the fiscal and service data necessary to substantiate a request for a halfway house program in Pima County. As a result of the presentation made, the legislature appropriated $178,000 to purchase land and buildings. The funds for the additional staff needed to operate the halfway houses will be taken from the surplus that has been accumulated to date as a result of the impact of the combined Mental Health Care Program.

DISCUSSION

Planning for the development of a unified system of mental health service delivery is a difficult task. The success of the Combined Mental Health Care Program in creating this unified system for the residents of Pima County can be partially attributed to the origins of the impetus for the creation of the program. Unlike the experiences in California, where the impetus for the development of a more unified system of care began at the state legislative level and came to the local communities through the Lanterman-Petris-Short Act, within Pima County its origins were in the community and were then directed toward the state level.

The early involvement of many citizens, who had concerns about the quality of mental health services available in the community and the misuse of the state hospital as a "dumping ground," was responsible for the grass-roots movement that eventually resulted in the creation of the Combined Mental Health Care Program. It is extremely doubtful whether this program could have been developed if the impetus for it had come solely from the state hospital or from the legislative level.

On the other hand, community interest and concern must be given support by the creation of appropriate incentives that will make the creation of a unified system of care worthwhile for the community. Professionals who are involved with different agencies and who have their own vested interests regarding the delivery of services can only be drawn together into an acceptance of the theoretical goals and practical consequences of a unified system of care if they are accompanied by the financial incentives that the Combined Mental Health Care

"Surplus" over "fair share"			$ 108,534

*20.3 percent of $9,486,946.

Program included through its relationship with the state.

In addition, incentives must also be present for the state hospital system if it is expected to cooperate in the creation of a unified system of care. In the case of the Combined Mental Health Care Program, these incentives were not overtly financial, but primarily programmatic. Prior to the institution of the Combined Mental Health Care Program, the state hospital was forced into a custodial role for many of its patients because of the large number who flowed into it not only from Pima County, but also from other communities in Arizona. Coupled with both an absolute and relative shortage of staff, it became extremely difficult for the state hospital to develop specific programs that met the needs of its patients.

The cooperation of the state hospital in the creation of a Combined Mental Health Care Program resulted not only in the implementation of an effective community program that provided locally based mental health services but also in the development of a deterrent to unnecessary state hospitalization, which helped bring the census of the state hospital within the therapeutic capability of the available staff. When this happened, the state hospital was able to develop specific therapeutic programs that met the needs of the specific patient groups that remained within the hospital, such as the chronically ill, the institutionalized, and the geriatric patient (4). Consequently, the cooperation of the state hospital in a unified system of care can enable it to shake off its previous image of a custodian to the mentally ill and to move toward acquiring a new image as a dynamic leader in the creation of therapeutically sound programs for the chronically ill.

Finally, the creation of a unified system of care, as exemplified by the Combined Mental Health Care Program, was also greatly aided by the availability of a "neutral" third party, which was able to mediate concerns and differences between the community and the state hospital and act as a catalyst for the development of this new system. In the case of the Combined Mental Health Care Program, the local medical school served in this capacity. However, in other communities, where a medical school may not be available, other types of agencies may serve comparable purposes. For example, a local health planning agency that has a mandate to coordinate mental health services within the community could also serve as the bridge between the community and the state hospital. Mental health associations, if they have a firm base and are accepted within the community, may also be an additional resource as a catalyzing agency in the development of the necessary relationships between the local community program and the state hospital program.

CONCLUSIONS

The development of community psychiatry and community mental health programs has often been called the "third revolution" in psychiatry. However, if this "third revolution" is to gain an adequate base and eventually establish itself as an accepted part of the total treatment spectrum, a "fourth revolution" will have to take place—one that will bring the community mental health center model into a unified system with the previously existing state hospital model.

The time is certainly not too soon for both local communities and state hospital programs to put away the competitive attitudes that have characterized their relationship since the development of the community mental health center program and to begin to move more effectively toward the creation of a truly unified system of care.

The Teaching of Psychiatry to Medical Students

BY JOHN ROMANO, M.D.

The author describes some of the changes that have taken place in undergraduate medical education in the past ten years and indicates some of the areas that will probably be touched by further change. Since these changes increase the need to develop a valid and reliable method of assessing the clinical performance of medical students, the author reviews some of the studies of this type that have been reported and the methods and instruments that they have used.

DURING THE PAST 25 years, at APA's annual meetings and in the published reports that emerge from these and similar meetings, attention has been drawn to the changes that have occurred in the teaching of psychiatry to undergraduate medical students in our nation. These comments include comparative observations of the teaching of medical students in the United Kingdom, Ireland, other Western European nations, the Soviet Union, and the Middle East (1–12).

More recently, in an autobiographic sense, I compared my initial experience in the field of psychiatry as a medical student 40 years ago with those afforded students of today (13). While there may have been exceptions, I believe that my experience as a student was quite representative of the form and content of the teaching of psychiatry to medical students in the early 1930s. Full-time faculties, particularly in the clinical disciplines, were rare indeed, and provisions for the serious engagement of medical students in the study and care of the mentally ill were even rarer.

What changes have taken place in the interim? Because of the establishment of psychiatric services in general teaching hospitals, and because federal funds made it possible to appoint increasing numbers of persons to full- and part-time clinical faculties, today's student is able to study and care for the mentally ill patient in the teaching hospital—that is, in the same setting in which he studies and cares for medical, surgical, and obstetrical patients.

It is in the traditional setting of the university teaching hospital that the medical student learns at first hand the nature of mental illness. It is here that he learns of the shame, guilt, anxiety, and at times the perplexity and despair of his patient, and it is here that he learns, too, of the effect mental illness may have on other members of the patient's family and other social groups. He has the opportunity to learn something of how aberrant mental behavior has been regarded in the past and in the present day. He gains firsthand experience in managing and treating patients who are delirious and demented, depressed, and hypochondriacal, and he senses something of the great enigma that is schizophrenia. He becomes aware of the universality of suicidal ideas, of the significance of suicide attempts, and of the fact that suicide is a major cause of death.

The student's experience in the university teaching hospital makes possible assignments to various clinical divisions of the teaching hospital; thus he is able to learn something of the uses and abuses of diagnostic and therapeutic procedures and of emergency, short-term, and long-term hospital care. He is also in a position to learn to be critically perceptive about these methods and can begin to measure the effectiveness of physical agents, drug treatment, and individual and group psychotherapy. In this work he also has an excellent opportunity to learn that man is a social animal, that his patient is a member of a group and of a family, and that the patient's distress and symptoms can be understood more clearly if they are dealt with in these social terms. Similarly, the student learns that he, too, is a member of a group in the hospital and the clinic. In this way he learns more specifically about his role, the tasks assigned to him, and those assigned to his associates.

Many students will have additional opportunities to work with chronically disabled persons, including the handicapped, the retarded, the chronic psychotic, the epileptic, and those with sensory defects. In this regard they will learn something of the psychology of illness and disability and of the coping capacities of patients with dis-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Romano is Distinguished University Professor of Psychiatry, University of Rochester School of Medicine and Dentistry, Strong Memorial Hospital, Rochester, N.Y. 14642.

abilities. Furthermore, it is in the teaching hospital that the student will face many patients who present diagnostic dilemmas, including those with intractable pain in whom evidence of structural impairment is minimal, patients with nonspecific symptoms of fatigue and restlessness and depression, and patients who are dying. He will also learn about the events, including bereavement, that affect those who care for the dying patient.

The unique contribution that psychiatry can make to the education of the medical student is to help him understand the differences between objective observation, participant observation, subjective observation, and self-observation. Skills in objective observation have been his principal heritage from his background in science, but as he learns other types of observation, he finds that this differentiation of his role function is necessary for him to understand his relationship to his patient and to his growing capacity for human intimacy in the specific task of becoming a physician.

Perhaps for the first time the student confronts the fact that there is no satisfactory unitary concept of human biology and that, in spite of the valiant attempts of general systems theorists, there has emerged no satisfactory language that does full justice to the biological, psychological, and social aspects of the human condition. This is best illustrated in attempts to explain the nature of the schizophrenic person and his family. Although much has been learned, the condition still remains enigmatic.

Most of us would agree that etiological considerations can be divided into three paradigms of patterns. The first is to the effect that schizophrenia is an organic disease and that there are genetic factors, metabolic and biochemical factors, and neurophysiological and neuropathological factors, or several combinations of these. A second notion is that schizophrenia is a purely psychogenic condition similar to what many believe underlies psychoneurosis. In this paradigm individual psychodynamic factors, family relationships, and social and cultural factors are included. A third is a general combination of the biogenetic and the psychogenic points of view, essentially indicating a diathesis plus stressor hypothesis.

Obviously, one of the central objectives of this learning experience is to assist the student to become critically perceptive of data and to acquire some notion of the emergence of ideas and practices in the field of his concern. More than in other fields, he must carry the anxiety that accompanies the uncertainty of his knowledge. In examining the general notion of personality he will learn of genic and ontogenetic factors in the growth, development, and decline of the person. From developmental physiology and psychology he will learn something of the various stages of the life cycle and of the role of the nervous system in this evolution. He will recognize that there are unconscious and preconscious factors, in addition to conscious factors, that determine human behavior. He will learn that the personality is integral and indivisible and that, to understand man in human terms, he must become informed of the interaction between man and his social environment. I believe that much of this helps the student to obtain a clearer concept of health as well as disease. It also helps him to understand that psychopathology is multiply determined.

CHANGE IN THE CURRICULUM

What is to happen now, and what of the future? With Heraclitus, I believe that change is inevitable. I have also learned that change may be for the better, for the worse, or, as the French told us years ago, it may lead to the same. Obviously, there will be continuous changes in curricular patterns since the curriculum is an instrument, a means to an end, not an end in itself. Just as a broad liberal education has as its end the preparation of the ideal citizen, so too the medical curriculum, at any one time, has as its objective the preparation of the ideal physician—one who is informed and sensitive and equipped to deal with the health issues of his day. Education in general, as well as professional and technical education, is the concern of many thoughtful citizens. There is considerable criticism of the medical profession from within its ranks and, more particularly, from the public and the consumer-patient. This has led those responsible for medical education to become involved more systematically in studies of health delivery systems. Much of the ferment in medical education today stems from the very great contributions made by new information and technology in physics and chemistry as they apply to biology and to medicine.

The concerns about health delivery systems and what to do with the prodigious increase of new information obviously affects the curricular pattern of the undergraduate medical program, and during the past ten years certain trends have become more apparent. These include reducing the total period of professional education from four to three years in the undergraduate assignment, with resultant reductions in the time of basic core assignments and with increases in elective assignments and the number of interdisciplinary courses. Students have been invited to make early commitments in terms of their special interests, particularly through the establishment of multiple tracks in the curriculum. There are at the moment about 25 schools that have established three-year undergraduate curricular periods. Coincident with this has been the truncating of the professional graduate educational period. The free-standing internship has been eliminated and there are attempts to combine undergraduate and graduate programs into a single system.

I shall not discuss any of these matters in detail, since I have done so on a number of occasions previously, except to raise again the question of what can be done to maintain present standards of quality in medical education (11–13). In my view, one of the major contributions that psychiatry has made to the education of the modern physician has been to inform him of certain fundamental aspects of the human and social aspects of biology. Psychiatry has been the principal agent that informed the student of the basic emotional and cognitive aspects of human interaction. From his study and work with

patients, the student learns of the significance of the effects of psychosocial events as these occur in the lives of his patients and their families. I believe that there are considerable risks in requiring early commitment of a student to selective, and at times restrictive, fields of interest, which may reduce his options early in his intellectual and professional life.

I believe the student should have the freedom to choose his career, but I would hope that his choice would be intelligent and informed and would emerge from the wide range of opportunities that medicine provides. I am concerned, too, that present trends seem to degrade those experiences in which the student acquires skill in clinical reasoning. No one would challenge the fact that the basic qualities of dependability, responsibility, and accountability—the hallmark of the physician through the centuries—are acquired from his daily work in the study and care of his patients and from his teachers, who have taught him by example as well as by precept. As must be evident, I am concerned about the increasing technology of medicine. With the proposed reduction of time for professional preparation, including the elimination of the free-standing internship, will the professional person of tomorrow be less well prepared as a generalist? Will he be less broadly civilized to meet the problems of his day?

As I mentioned earlier, I am certain that change is inevitable and necessary in order that we may adapt to, and master, the health issues of the day and of tomorrow. But, in short, today's students have different experiences than most of us had 40 years ago. The changes provide substantial contributions to the education of the physician, and psychiatry has played a significant part in their achievement. In turn, the psychiatrist has had the benefit of a broad liberal education in medicine. While it is true that each generation is apt to exaggerate its importance and to overestimate its contribution to the common good, there is the wish, a very genuine wish, that whatever changes are to take place will enhance and develop further, not diminish, the educational opportunities of today's students. With the changes contemplated, there appears to be an even greater need to develop a reliable and valid method of testing the performance of our students in what can be called their clinical operations. With fragmentation of the curriculum, with interdisciplinary courses, with greater election, and with some disregard of the clinical disciplines, there is an even greater need to determine what is essential and fundamental in the education of the physician-to-be and what measures the school can take to assess these essential and fundamental qualities before certifying him as a Doctor of Medicine.

ASSESSING CLINICAL PERFORMANCE

The clinical performance of our students has been the concern of many of us. During the past 30 years we have observed medical students, interns, and house officers from many schools in this country and from many schools abroad and have compared their clinical skills. We also have accumulated a considerable number of self-report statements of graduates of our schools, comparing themselves with students from other schools as they meet each other in clinics and hospitals throughout the nation and the world. While this information is unsystematized and not very readily transmissible, it shows clearly that as yet there is no adequate substitute for consistent supervised instruction of the clinical student who is significantly and seriously engaged with, and responsible for, the care of his patient and the patient's family.

The limitations of the written tests are well known, although the introduction of psychiatry, in 1962, as a major independent subject in the National Board Examination, Part II, now enables the faculty of one's own school to compare the results of its students' performances with those from other schools, which remain anonymous, and also to obtain more detailed analysis of the examination responses in order to learn the strengths and weaknesses of one's students in the various subsections of the test. About 15 years ago we constructed a method for evaluating the clinical performance of our medical students, and in 1962 Salzman and I reported on our experiences (14).

The rating scale, as it finally emerged, consisted of nine categories and the student was rated in each category on a nine-point scale, ranging from "failed" to "outstanding." The nine categories included responsibility, knowledge of medical facts and the physical examination, knowledge of psychopathology and psychodynamics, psychological perceptiveness, relationship with patients, relationship with relatives, relationship with staff, the quality of the write-up, and growth of the student's performance. The scale adopted was better able to obtain normal distribution of grades than were earlier, more subjective methods. Grading was done multiply by members of the house staff and the senior faculty, who worked intimately with each student.

There still remains the question of rater reliability. It was the studies of Geertsma and Stoller in 1958 and 1960 (15) that set the stage for various later tests of assessing clinical psychiatric skills. The assessment procedure utilized filmed psychiatric interviews, objective evaluational ratings, and objectively derived criteria. They reported that highly significant differences were found between residents and freshmen, residents and volunteers, seniors and freshmen, and seniors and volunteers. Salzman and Goldstein, in our department at Rochester, reported on changes in clinical judgment as a function of psychiatric education (16, 17). They used a single tape-recorded psychiatric interview with a patient, which was played to a number of groups of students, residents, and faculty, who were then asked to rate the patient in terms of a large group of psychiatrically relevant statements. They also found a positive increment with greater psychiatric education and experience. Langsley (18) and Monroe (19) also used filmed interviews in attempts to approximate a measure of clinical skills and to go beyond measurement of only factual knowledge.

Thurnblad and his associates (20) have cautioned psychiatric educators about the use of simulated examinations as measures of proficiency in the acquisition of

clinical skills and believe that some measurement of student performance by direct observation is essential.

As I mentioned earlier, I am convinced that change is inevitable. I also believe that, if change is to take place, attention must be paid to the reasons for the change and the consequences of the change. The medical curriculum will always be in a state of flux, depending upon the amount of information, technical knowledge, and money available to it. Several of us have contributed to a more intimate, harmonious, and effective exchange between medicine and psychiatry in this second third of our century. I, for one, would hope that this will not be diminished. In the broad sense, I hope that we will continue to recognize and respect the individual differences between our students and to provide each of them ample opportunity to become all that he is capable of becoming. In practical terms, this means that the student should have sufficient opportunity to become intelligently informed before making his career choice and, if he is destined to become a clinician, that is, one who is directly and intimately engaged in the study and care of the sick person and his family, that he should have the full measure of the experience that is basic, fundamental, and unique to this role.

Medical Students View Clinical Psychiatry

BY SIDNEY L. WERKMAN, M.D., STEPHEN LANDAU, M.D., AND HAROLD WAKEFIELD, M.D.

To investigate the relevance of various components of psychiatric teaching to the later practice of medicine, the authors asked 126 medical students to rate their perceptions of clinical psychiatric work and to assess their view of psychiatry before and after a clerkship. The students rated their experiences in descending order of usefulness as follows: outpatient treatment, emergency service, didactic seminar, child psychiatry, and inpatient treatment. They also recorded statistically significant changes in their perceptions of themselves with regard to psychiatric patients as they gained clinical experience.

THE STUDENT is both the subject and consumer of our efforts to teach psychiatry in medical school. Although

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this work was done, the authors were all with the Department of Psychiatry, University of Colorado School of Medicine, 4200 E. Ninth Ave., Denver, Colo. 80220, where Dr. Werkman is Professor and Drs. Landau and Wakefield were Chief Residents.

This study was supported in part by Public Health Service grant MH-05992 from the National Institute of Mental Health.

The authors wish to thank Gary O. Zerbe, Instructor in Biometrics, for his advice on the statistics and James Huber for his assistance in data reduction.

there has been a good deal of research into variables that affect student performance in psychiatry (1–4), we have little more than anecdotal and often idiosyncratic data on how medical students themselves perceive the usefulness of our teaching. One way to learn more about the appropriateness and effectiveness of our teaching principles and methods is to study the student's response to them.

In order to gain more precise information on medical students' opinions about the various components of their work in clinical psychiatry, we have devised a number of rating scales that attempt to relate the usefulness of psychiatric teaching to the later practice of medicine and that examine possible changes in the student during his clerkship. Obviously, these ratings tap a conglomerate group of factors including the student's interest, teacher popularity, chance, and anticipation, as well as the stated variables of "usefulness for the practice of medicine." A retrospective study after the student has been practicing medicine for some years would be necessary to give more powerful data on the questions asked. However, even this kind of study would be inadequate, since a physician's cognitive response would have to be matched against such other criteria as evaluating the quality of his actual clinical practice and ratings by external observers.

Since we cannot easily mount such a study, we offer the current one as a starting point for ongoing research. One point in favor of this methodology is that senior medical students at the University of Colorado School of Medicine are assigned to clerkships in medicine, surgery, obstetrics and gynecology, and pediatrics before they come to psychiatry; they thus have some realistic basis upon which to make judgments about what aspects of psychiatric knowledge they will need in their future medical practice.

GOALS

Before stating the results of our research we will give an overview of the goals and framework of our clinical teaching, for students only learn, if we are fortunate, what we attempt to teach (5). After a first-year course titled "The Human Life-Span" and second-year courses in psychopathology and psychophysiology, we divide our clinical goals, albeit arbitrarily, into external and internal ones.

The didactic or external goals are as follows: 1) knowledge of the spectrum of clinical psychopathology and psychiatric disorders; 2) understanding the natural history of psychiatric disorders (i.e., concepts of cure, adaptation, recovery, and residual deficit); 3) recognition of the significance of developmental phases, family structure, and social networks in psychiatric disorders; 4) experience with the dynamic interaction over time between the student and patients and the effective therapeutic use of that interaction; 5) management of psychiatric symptoms by psychotherapeutic means and the informed use of psychotropic drugs; 6) knowledge of the role models of psychiatrists, psychologists, social workers, and other mental health workers for later collaboration and emulation; and 7) preparing for the practice of medicine in a fashion that will facilitate the treatment of many psychological problems concomitant with physical illness, consultation with mental health workers, and the referral and reacceptance of psychiatric patients.

Since we view the clerkship primarily as an opportunity for medical students to gain intimate experience with patients, we have formulated several "internal" or intrapsychic goals for our teaching. They are defined as: 1) becoming more comfortable with psychiatric patients and not viewing them as "alien" (i.e., as fit subjects only for "alienists"), 2) becoming more knowledgeable about and accepting of the conflicts within oneself, and 3) learning to interact psychotherapeutically with patients without incurring undue anxiety or disabling defenses in oneself.

TABLE 1

Students' Ratings of the Usefulness of Clinical Psychiatry Sequences for the Practice of Medicine (N = 126)

Sequence	Mean
Outpatient clinic	4.94
Emergency room	4.68
Didactic seminar	4.61
Child psychiatry	4.30
Interview observation	4.10
Inpatient wards	4.09

RESULTS

We attempt to approach these goals through several teaching activities. Each medical student spends a full-time six-week clerkship in the psychiatry department during his senior year. His time, which is heavily weighted toward individual supervision and work with patients (and cannot be detailed in a short paper) is divided as follows: inpatient service, 60 percent; seminars and didactic sessions, 15 percent; child psychiatry, 10 percent; outpatient department cases, 5 percent; emergency room, 5 percent; and community psychiatry, 5 percent.

Each group of students rates these experiences anonymously, using a six-point scale ranging from "very useful" to "minimally useful." The categories the students rate include inpatient ward, outpatient work, child psychiatry, interviewing conference, family diagnosis, emergency room, didactic seminar, community psychiatry, and drug seminar; they are also asked for a global rating covering the entire clerkship.

In addition to these ratings we have considerable opportunity to discuss the clerkship with individual students and their supervisors. Table 1 shows that students rate outpatient work, emergency room experience, and a weekly didactic seminar (in which such topics as clinical aspects of child development, character types, syndromes, psychoactive drugs, and sexuality are discussed) highest with regard to their projected usefulness in prac-

TABLE 2
Student Views of Clinical Psychiatry

Items Rated	Clerkship	
	Beginning	Conclusion
Anxiety level with patients	3.59	3.51*
Empathy for patients	4.22	4.83*
Interest in psychiatry	4.33	4.71*

*Difference significant at p > .001 level, using two-tailed t test.

ticing medicine; they rate child psychiatry next and one-way screen interview observation and inpatient work lowest. These groups separate at the p > .05 level of probability using the Scheffe method for calculating analysis of variance.

From the ratings and our individual observations we tentatively concluded that students value most highly those experiences which present them with direct patient involvement and responsibility (6). For example, they consistently rated the outpatient clinic and emergency room experience, where they diagnose and treat patients as primary physicians or therapists, the highest in usefulness. Experiences that are closest to the medical model of their usual functioning as student physicians are the most congenial to them. Students are the most comfortable when a patient who is anxious and seeking help comes into "their " office. Apparently they also appreciate the structure and data of didactic seminars that explicate and supplement the major emphasis on patient-student involvements.

To assess student opinion about personal changes (internal goals) with regard to psychiatry and psychiatric patients during the clerkship, at the beginning and at the conclusion of the six-week clerkship, we ask them to anonymously rate the following items: "anxiety level with psychiatric patients"; "feelings (or empathy) toward patients with psychiatric problems" (rated from positive to negative); and "level of interest in psychiatry, psychiatric knowledge, and techniques." We do not show students their original ratings when they make their final ones (see table 2).

In all three dimensions the difference between the beginning and end of the clerkship was statistically significant at the p > .001 level of confidence, using a two-tailed t test. Anxiety level decreased; empathy or feeling for psychiatric patients increased; and interest in psychiatry all increased by the end of the clerkship.

Although we must emphasize that we are tapping opinion rather than observation, these results, when combined with supervisors' impressions and students' statements, do suggest that we are approximating the clerkship's internal goals, which center on helping the student become more clinically identified with the field of psychiatry and with psychiatric patients.

To gain further insight into the importance of the clerkship for students, we ask the following question at its conclusion: "What has been the single most significant experience or aspect of the psychiatric clerkship?"

The approximate percentage weights of the responses follow: *Individual supervision*—30 percent ("the one-to-one supervision by a psychiatric resident"); *Sensitivity group*—15 percent ("the leaders deserve a gold medal in the psychic winter olympics"); *Patient crises*—10 percent ("my patient made a suicide attempt and my self-searching"; "trying to reach a schizophrenic patient"; "when a patient's husband called and pleaded for help, I realized these people's problems are quite real"); *Self-examination*—10 percent ("I looked at myself for the first time in medical school"); *Positive patient movement*—20 percent ("being on my own with a patient and feeling good about it—for him and me"; "I began to think that maybe I could do something with psychiatric patients"); *No significant experience*—10 percent; *Miscellaneous*—5 percent.

DISCUSSION

A number of generalizations can be tentatively deduced from these data.

1. The high ratings given the emergency room and outpatient clinic rotations suggest that close, responsible involvement with patients is a most highly prized aspect of a psychiatric clerkship. In both of these services the student is the primary physician, and even though these very experiences mobilize a great deal of anxiety, the ratings given them highlight their importance for learning.

2. The total immersion in patient care offered by this kind of clerkship provides the student with an opportunity for involvement and informed self-searching through the use of supervision that is rare in other aspects of medical education. That at least 65 percent of the students rate some aspect of intimate patient observation or self-examination as the most important experience during the clerkship supports this view.

3. Supervision by residents is an effective method of increasing student involvement in psychiatry. Perhaps the issue is merely a contemporary historical one, but these data and our impressions suggest that students look for lateral or peer supports and teaching experiences even when more experienced professionals are available to them. Students seem to feel that psychiatric residents, who are often only one year ahead of them (since increasing numbers of residents do not take an internship), are closest to their concerns and needs. Our successful use of resident-run group sensitivity sessions for students is further evidence of this phenomenon.

4. The consistent statistically significant increases in interest in psychiatry as a field and in positive feeling or empathy for psychiatric patients during the clerkship offer some comfort to those who teach. Though a number of students in these "blind" ratings recorded a decreased interest or empathy from the beginning to the conclusion of their clerkships, the general trend is in the direction we would hope for. Since our work, more than that of many specialties, requires the cooperation of other physicians, we believe it important that students show some in-

formed tendency to identify with psychiatric patients and the field of psychiatry.

5. Observations in case conferences and didactic sessions, examination results, and the general appraisal of student knowledge lead us to conclude that many students do not remember and often cannot use concepts about dynamic psychopathology and development as they start the psychiatric clerkship. We have little hard data to support this view, although we think it is an important one that may lead us to restructure the courses offered in the first several years of medical school, particularly if other departments of psychiatry come to similar conclusions. The statistically significant rating at the start of the clerkship of lower interest in psychiatry as a field offers some buttressing to this point of view.

While earlier courses teach important general concepts, they apparently do not engage the student's continuing attention and interest. If this is so, the experiential aspect of the clerkship bears a heavier responsibility. In a charitable view, the knowledge gained from preclinical courses may follow the "positively accelerated curve" of learning, described by Dykman and Reese (7), that explains students' attempts to master material which is difficult, detailed, or conceptually novel. This view may also help explain something about the poor recall of material from earlier psychiatry courses.

CONCLUSIONS

We have relatively little systematic data on how medical students view the usefulness of their experience in clinical psychiatry. Because such data would help us structure our teaching more effectively, we have had students rate a number of dimensions of their clinical work around the concept of "usefulness for the practice of medicine."

The statistically significant results obtained suggest that students believe direct patient involvement and "medical model" responsibilities will have the greatest usefulness for the later practice of medicine. In a program organized around the concept of experiential teaching, students showed significant increases in interest in psychiatry and empathy for psychiatric patients and significant decreases in anxiety by the end of their clerkship period.

Psychiatry in the Undergraduate Medical Curriculum

BY MORTON F. REISER, M.D.

Psychiatry in its teaching activities has the obligation to develop effective ways of bridging vast theoretical, empirical, and philosophical gaps that exist between nonpsychiatric physicians and biological scientists (without backgrounds in behavioral science) on the one hand, and behavioral and social scientists and other nonmedical professionals engaged in health care (without backgrounds in biology and medicine) on the other hand.

THE PROBLEMS AND THE WORRIES as well as the sense of excitement, challenge, and opportunity that we confront as psychiatric teachers in the seventies are part of the very real (and I think very urgent) identity crisis in which psychiatry and other mental health professions find themselves today. Among the multiple factors contributing to this general situation are several of particular relevance for the undergraduate medical curriculum.

To a large extent psychiatry is becoming a principal

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Reiser is Professor and Chairman, Department of Psychiatry, Yale University School of Medicine, 333 Cedar St., New Haven, Conn. 06510.

custodian of the humanistic aspects of patient care in general hospitals and responsible for teaching its principles and practices to medical students. This problem is being magnified by the elimination of the internship requirement in a number of specialty areas as well as by an increasing need for programs that will train primary physicians.

The implications of developments in the social and community psychiatry movement, as well as changes in contemporary society, compel us to reconsider our ideas concerning the nature and cause of disturbed behavior. We must broaden the range of the responsibilities and concerns of psychiatry as a field, while paying greater attention to problems of health care delivery, to prevention, and even to participation in developing comprehensive health maintenance programs.

This rapid and extensive expansion of mental health practice into social and community psychiatry and into preventive mental health programs has led to inevitable blurring of professional role boundaries. But psychiatry (by virtue of its roots in neurobiology and medicine as well as psychology) stands as the mental health discipline best equipped to establish, nurture, and maintain realistic functional links with medicine and medical practice. As a result, psychiatry in its teaching activities has the obligation to develop effective ways of bridging the vast theoretical, empirical, and philosophical gaps that exist between nonpsychiatric physicians and biological scientists (without backgrounds in behavioral science) on the one hand, and behavioral and social scientists and other nonmedical professionals engaged in health care (without backgrounds in biology and medicine) on the other hand.

This latter (bridging) task is being rendered vastly more complex and demanding by the thrilling but relentless information explosion in the neurobiological, behavioral, and social sciences and by the concurrent expansion and increasing sophistication of related technologies. In its broad contemporary context the field of mental health can be regarded as encompassing a range of disciplines extending from molecular biology and genetics at one end, through general biology, medical biology, neurobiology, psychology, psychoanalysis, social psychology, sociology, and anthropology, and to political and administrative sciences and the emerging new applied science of urbanology at the other. The range of disciplines and information is indeed vast.

Meanwhile, the information explosion has necessitated fundamental changes in pattern and content of the undergraduate medical curriculum, within which our teaching of psychiatry must be fitted and accommodated (e.g., the new track curriculum).

CONTENT OF THE CURRICULUM

It is not difficult to construct a list of topics and areas that psychiatry should include in its part of the undergraduate medical curriculum. First, it must teach the basic biological, psychological, and sociological aspects of the behavioral sciences that are relevant and necessary for developing in the student a theoretical base for understanding human behavior in health and disease.

Second, it must teach the basic knowledge of clinical psychopathology and impart the technical interviewing skills that all physicians should have in order to make diagnoses—to recognize and deal with behavioral emergencies, to make effective referrals, etc.

And third, it must impart to students an intimate working knowledge concerning the interaction of emotions and physiologic functions in health and disease: both the impact of illness upon the psychological state of the patient and the role of emotions in medical pathogenesis and the cyclic feedback interplay between these two kinds of reactions. This means preparing future physicians (particularly primary physicians and generalists of the future) to apply modern psychological, psychophysiological, and psychosocial understanding in all phases of medical practice: diagnosis, treatment, and research. As mentioned earlier, teaching around the issues that are related to the ***human*** needs of individual patients will be a major responsibility of psychiatry during the next decade, and it will require considerable manpower and resources. Furthermore, the increasingly important role of liaison psychiatry in the general hospital constitutes an urgent research challenge; studies are needed to broaden and deepen our understanding of the interactions between emotional and physiological states not only within individual patients, but also within the hospital viewed as a social system. This involves the interactions within the social ward milieu between staff and patients and the impact of these transactions upon physiologic systems and upon the clinical course of disease in individual patients.

I will not dwell on specific details of this list, nor do I feel prepared to attempt even a preliminary scheme for fleshing it out and updating it in accord with contemporary demands. These issues have been thoughtfully and extensively dealt with by others (1–3). Rather, I want to highlight some of the critical issues that demand consideration before these other matters can be dealt with. We must first be clear about what it is we have to teach, as well as what psychiatry and psychiatrists are to be and what they are to do in the professional world into which our students will graduate.

MAN IN HIS BIO-PSYCHO-SOCIAL FIELD

States of health and illness can be fully understood only in terms of three parameters: the biological, the psychological, and the social. Comprehensive health practices require a repertoire of skills pertinent to dealing with problems in all three of these critical dimensions. Clearly, an ever-increasing variety of professionals and specially trained workers from an increasingly wide spread of disciplinary backgrounds will be needed to cope with these problems, and no single specialist (including the psychiatrist) can or should be expected to attain authoritative mastery across the entire spectrum.

Man in his bio-psycho-social field can be viewed as

part of an open system that allows for an uninterrupted two-directional flow of information and energy transactions extending from the deepest and most minute recesses of the body, i.e., from intracellular metabolic processes, all the way to the social field in which the individual lives, including the cultural forces and even the historical forces that helped to shape that culture.

At the center is the brain, which somehow mysteriously subserves the higher mental functions (the province of the clinical psychiatrist, psychoanalyst, and psychologist). The higher mental functions in turn subserve the interpersonal relations and the individual transactions with the social environment, including immediate family, small social groups, and society at large (behavior). The brain, on the other hand, also somehow mysteriously "transduces" (4) immaterial (nonphysical) social experience into physiological (physical) events within the central nervous system. These events may then initiate physiologic change throughout the body; brain function can in turn be affected by physiologic changes in the periphery of the body, these exchanges being negotiated by the central and autonomic nervous systems and the neuroendocrine systems that link the brain with the entire organism, including its most remote and minute recesses.

Psychiatry, in addition to doing its own thing, will need to take on new roles that will facilitate linkages and provide communication bridges in theory, practice, training, and research between vast numbers of workers from a wide variety of disciplines, all of whom will have important roles in the mental health field as so broadly defined. The fact that the psychiatrist is a physician with skills and understanding related to the function of the brain and its relation to the body as well as to mental and social life constitutes his unique qualification for special and key roles in the complex, sprawling mental health field.

In respect to theory, the psychiatrist as physician can help in efforts that aim to provide conceptual linkages between biology on the one hand and the social sciences on the other. In practice, the psychiatrist will have to function as coordinator between basic biologists who do not (and need not) have training or an interest in social science and mental health workers from the social field who do not (and need not) have training in medicine or biology. In teaching and training, psychiatrists will need to contribute to programs that prepare not only psychiatrists but also workers in the nonpsychiatric allied professions. In research his role may be of a bridging, coordinating, collaborating nature; sometimes he will most appropriately assume an executive role. Each individual psychiatrist of the future will need to be trained in some realistically defined area or sector of the broad field (e.g., a subspecialty) and also to work in new roles that will facilitate linkages and provide the communication bridges already described.

Obviously, no one discipline can be expected to master and direct the whole thing. Psychiatrists will probably lead in many sectors, follow in others, collaborate in others, and play executive-coordinating and educative roles at other appropriate points.

Whatever his special area, the irreducible core or base of training for every psychiatrist should prepare him for his role as a *physician*-clinical mental health specialist who will be able to talk across, around, and about the mind-brain and the brain-body articulations.

This, I think, is what we must constantly keep in mind as we try to grope our way through the training challenge of the seventies. Psychiatry must not lose its connections with its central neurophysiological and medical roots and underpinnings.

CONCLUSIONS

Accordingly, at the moment I conclude that beyond the relatively simple issues of content and technical skills noted earlier in my list, it will be of utmost importance for us to impart to all students of medicine concepts and perspectives that they may then use: 1) to aid them in their attempts as physicians to deal with the psychological and humanistic aspects of their work, 2) to assist them in their attempts to deepen and extend their conceptual understanding and appreciation of the complexities of mind-brain-body interrelationships in health and disease, and 3) to provide a conceptual schematic matrix into and onto which they can superimpose, fit, and integrate all of the new information that is sure to emerge in the years ahead as the information explosion continues.

A Test of Clinical Learning by Medical Students

BY ROBERT J. THURNBLAD, M.D., HYMAN MUSLIN, M.D., AND JOHN LOESCH, M.D.

The authors compared the performance of different classes of medical students on an examination using videotaped clinical material. Although the examination was designed to test some aspects of clinical learning, the principal finding was that students achieved high scores at the end of two years of preclinical work; after that no further increment was found. This points up the need to evaluate test instruments carefully and especially to continue direct assessment of students doing clinical work.

ONE OF THE MAJOR RESPONSIBILITIES of medical schools is that of certification—that is, the issuing of a public statement proclaiming that a student has reached or exceeded a certain level of performance in the general practice of medicine. The granting of the degree certifies that the student has mastered a given body of medical knowledge, has acquired the ability to function effectively in the clinical situation, and possesses certain other qualities or attitudes felt to be necessary in a physician. The problem of assessing these criteria in our students remains a major concern for medical educators. As we become more sophisticated in the application of principles of teaching and learning to our curriculum design and instructional methods, it also becomes clear that we must also be able to evaluate the complex aspects of clinical learning. It is important that our assessment methods be reliable, that they validly measure desired objectives, and that they be efficient in the sense that they can be applied to large groups in a limited period of time. Our students also rightfully demand that tests provide educational feedback (1).

Several years ago Miller and associates wrote:

> Written tests should certainly be used to measure knowledge, but other devices are needed to measure the students' acquisition of skills, attitudes, interests, habits, and ethics. Because these latter qualities are difficult to measure, while the measurement of information learned is relatively easy, a faculty may conclude that if a student acquires information the other objectives are being met. But this is not the case. The excessive or exclusive use of objective or essay examinations to measure the student's progress can lead only to the misconception that the major goal of instruction is the successful completion of tests in several subject areas (2).

The authors are all with the Department of Psychiatry, Abraham Lincoln School of Medicine, University of Illinois, 912 S. Wood St., P.O. Box 6998, Chicago, Ill. 60680, where Dr. Thurnblad is Associate Professor of Psychiatry, Dr. Muslin is Professor of Psychiatry, and Dr. Loesch is Assistant Professor of Psychiatry.

There have been several studies by psychiatric educators who have tried to devise methods of assessing clinical psychiatric skills. Direct observation of a student's interview behavior has been done, but it poses problems related to inefficiency and to difficulties concerning the reliability of raters. In 1958 and 1960 Stoller and Geertsma (3, 4) designed the prototype of several tests, using filmed interviews and a long list of statements permitting a description of patients including their defense mechanisms and, to some extent, their psychodynamics. They were able to demonstrate that changes occurred during the course of medical school—the seniors making judgments that more nearly approximated those of experienced psychiatrists. They also felt that this method measured skills beyond factual knowledge and that it measured something more than common sense or ability to take examinations.

A comprehensive study of changes in clinical judgment as a function of psychiatric education was done by Salzman and Goldstein (5) at Rochester, N.Y., using statements like those of Geertsma and Stoller (4) with an audiotaped interview. They also found a positive increment with psychiatric education and experience, although there were a few exceptions that will be discussed later. Langsley (6) also confirmed that filmed interviews could be used to show differences among different groups of students, interns, or residents. Using the films designed by Strupp to measure skills in psychotherapy, Monroe (7) correlated film test responses with clerkship evaluation and factual knowledge. He found a better correlation between clinical test performance and clerkship performance than between factual examination and clerkship performance. All of these studies were attempts to approximate a measure of clinical skills and to go beyond measurement of just factual knowledge.

Despite these promising studies, the integration of the assessment of clinical skills into the certifying examinations of most schools has not been impressive. At the Conference on Psychiatry and Medical Education held in 1967 (1), the commission on methods reported on the senior examinations in psychiatry of 60 medical schools. Eleven reported they utilized the National Board of Medical Examiners score in psychiatry as their evaluation criterion. Thirty-three of the 60 sent copies of their senior examinations. The commission reported: "By and large, the examinations submitted by the thirty-three schools consisted of questions assessing the recall of relatively isolated fragments of information" (1). The overwhelming majority of the examinations were objective, with relatively simple item types (e.g., true-false, sentence completion, multiple choice, matching). Only a

handful of the examinations reflected the work of those with special experience and competence in examination construction. In most of the examinations there was little resemblance between the test items and the goals and objectives of psychiatric education specified in the Conference on Psychiatric Education held in 1951. "The disparity between our previously stated goals and our examinations as a whole constitutes a major problem," was one of the conclusions of the 1967 conference (1).

To bridge the gap between the yet unsolved problems related to the direct measurement of clinical skills and the tendency of written examinations to be limited to the assessment of factual knowledge, test questions are being developed that require problem solving in simulated clinical situations (8–10). The present study deals with the performance of medical students in a simulated clinical situation—a videotape of a psychiatric interview. It is an attempt to approach the objective measurement of psychiatric clinical skills.

METHOD

An examination was designed that was thought to approach problems encountered in an actual clinical setting. A videotaped psychiatric interview was shown and students were tested on certain observations, hypotheses, and inferences covering a general range of clinical psychiatry, emphasizing psychodynamic observations and principles. A series of statements was composed by the authors (all of whom are experienced in clinical work, teaching, and evaluation design) and the students were asked to choose among the following:

1. if the statement describes *directly observable* behavior and/or *summarizes specific statements* made by the patient;
2. if the statement represents an *interpretation* that can be inferred reasonably from what occurred during the interview;
3. if the statement is *contrary to the evidence* and can be rejected on the basis of what occurred during the interview;
4. if the statement cannot be supported or refuted either by direct observation or interpretation of what occurred during the interview, i.e., there is *insufficient data* to judge the validity of the statement.

We believe this type of examination requires a combination of observational skills, understanding of psychiatric knowledge and theory, and (on some items) a degree of empathic understanding. We also believed that the test approximated a clinical situation because it used a videotape of actual clinical situations, it required the students to differentiate between observation and inference, and it required them to identify the data or reasons for their choices.

The test was given to five groups of students: entering freshmen, freshmen, sophomores, juniors, and seniors at the end of that year of education. The test was also given to a group of faculty to test its validity.

The "correct" answers were those selected by the authors after careful scrutiny of the tape and transcripts. Those items which appeared ambiguous to the faculty were deleted; there were no items in which a high number of the faculty selected a choice other than that chosen by the authors.

RESULTS

The means for each group were determined and compared using Duncan's Multiple Range test as modified for the situation in which the number of observations per group are unequal (10, 11). The means for the different groups were: entering freshmen: 46.1; freshmen: 53; sophomores: 58.1; juniors: 57.2; seniors: 58.4; faculty: 63.

Using this test, any two means not underscored by the same line are significantly different ($p = .05$). Any two means underscored by the same line are not significantly different. Thus there were significant increments in mean scores between entering freshmen and freshmen and again between freshmen and sophomores. There were no significant differences between sophomores, juniors, and seniors. The faculty mean score was significantly higher than that for all groups of students.

Two findings appear to stand out from these results: first, the test does appear to be a valid and useful measure of combined observational skills and psychiatric knowledge, and we find the expected improvement in scores by freshmen and sophomores, indicating that the desired learning has occurred. Second, however, we find no change between sophomores and groups of students at the clinical level (juniors and seniors) on an examination that was intended to simulate a clinical task and measure clinical skills.

DISCUSSION

The students as a whole, including the clinical students, performed well on the examination—that is, the scores of sophomores, juniors, and seniors approached those of the faculty. However, the principal finding was that clinical experience in psychiatry and/or other disciplines did not enhance student performance. Our findings corroborated those of Salzman and Goldstein (5), who used an audiotape and statements modeled after those of Geertsma and Stoller (4). They also found a plateau effect at the sophomore, junior, and senior levels. Others have found a graded improvement throughout the four years of medical education. However, we believe it is important to emphasize that a test designed to evaluate clinical skills may turn out instead to be a useful instrument for evaluating the knowledge and observational skills of preclinical teaching but may not measure what (if any) learning occurs during clinical work. We have considered the following hypotheses to explain the plateau effect for sophomores, juniors, and seniors:

1. We may have reached a fairly high plateau (sophomore, junior, and senior scores approximate faculty scores).
2. Freshman and sophomore courses were taught by the people who wrote the exam, while clinical students

were taught by a diverse group of faculty and focused on therapy with a small number of patients (however, all students were taught by the authors at some time and clinical students did have some further didactic work as well as patient contact).

3. No further learning occurs.
4. Learning that does occur is not measured by this test.

We believe that the last is the most likely possibility. Direct observations of students at work with patients, other types of tests, and student ability to observe data and formulate diagnostic and dynamic hypotheses all seem to improve during clerkship.

In watching a videotape, the student is asked to identify with the interviewer in such a way that his findings can reflect empathic as well as cognitive modes of observation. In order to obtain complete observations, an interviewer must include observations in which he can introspect vicariously and thus can get close to what the patient is experiencing from moment to moment. This hoped-for result in watching a simulated situation is seldom reached at a level that mimics the actual clinical encounter with a patient.

Our anecdotal finding through the years has been that students' observations during "watching" never match their observations while "doing." Sometimes their reactions are so influenced by their anxiety over data gathering and difficulties in their subjective responses that their observations are grossly inaccurate. At other times their observations correctly reveal empathic modes of observation. We have seen the difficulties in observation for the past several years while watching our freshmen students conduct diagnostic interviews. The concern of these preclinical students about the mechanics of data gathering and their uneasiness over the role of data gatherer so influence their observing capacities that their ability to see behavioral data is quite limited. Watching a videotape equalizes the situation so that less advanced students with clinical sophistication can better compete with advanced students. What was being tested was the student's ability to evaluate data presented in a relatively neutral way—i.e., he was a passive observer of a videotape. We recognized that we were not attempting to assess the student's ability to obtain data or otherwise perform in the actual clinical setting. However, we must recognize that we are still short of our goal of evaluating the student's ability to evaluate data and form hypotheses in a true clinical encounter.

Evaluation of psychiatric learning has in the main used instruments to measure outside knowledge or data that may or may not correlate with actual clinical proficiency. In psychiatry, clinical proficiency begins with the capacity to observe behavior during an interview (12). The next set of skills and knowledge that comes into play deals with the ability to collate the observed data into a frame of reference for understanding, ultimately leading to an appropriate therapeutic rationale. As noted previously, since many factors may interfere with the data-gathering process in such a way that the capacity to observe is interfered with, the capacity to observe during the interview cannot be taken for granted.

Some tests have been designed that correlate with direct observation of a student's performance, but an exceedingly high correlation would have to occur to justify their use as a valid measure of students' actual clinical performance. Simulated patients, patient management problems, and computerized patient responses offer some promise and need further study. However, we feel it is vitally important to attend to the operational aspect of psychiatric learning in which an appreciation of the ongoing state of the patient is essential in assessing the emotional status. Thus, in our view, measures of evaluation to accurately assess learning of clinical psychiatry must include instruments to evaluate the student's performance with real patients.

Psychiatry in the Functionally Organized Undergraduate Curriculum

BY ROBERT E. BECKER, M.D., RONALD M. WINTROB, M.D., ROBERT CANCRO, M.D., AND JAMES R. STABENAU, M.D.

The functionally organized curriculum permits the integration of psychiatry into most of the courses that comprise the first two years of medical school. Rather than presenting psychiatry to the student as a separate discipline or centering the acquisition of interpersonal skills around specific psychiatric diseases, this system introduces psychiatric concepts in their natural context, as they arise in conjunction with disease in functioning human organ systems.

PUBLIC REACTION to the Flexner report turned American medical schools to their present intensive utilization of the physical medical sciences as the basis of the preclinical curriculum. Traditionally the prospective physician is successively trained in the theory, data, and research methodology of each of the basic medical sciences. This has better prepared our students for graduate study than for coping with the human, social, organizational, and political aspects of health care.

There has lately been a trend away from the traditional medical curriculum of two years of preclinical study in basic sciences and two years of rotation in clinical services. In its place there has been developed an abbreviated core curriculum, followed by multiple tracks, one of which the student selects as an area of specialization. A second important change is emerging as medicine redefines its traditional humanistic goals to deal more broadly with social issues and human values. This involves the addition of socially based goals to the traditional objectives of a basic medical science program.

The 1960s can be described as a time of social turmoil manifested in widespread, often diverse social movements seeking reform in the health, social, welfare, political, and economic spheres. Medicine was not immune to the reforming fervor of this period. Medical students and young faculty activists raised questions about the responsibilities of the medical profession. Attention was directed toward providing medical services to the indigent, the problems of the urban ghetto, serving the rural poor, fees for service, and the impact of hunger, family planning, racism, housing, and environmental conditions on the quality of human life.

While this might be called social humanism, there has been increased attention to a value-oriented humanism. This is supported by the impact of the dramatic technological advances of the past decade. These advances raise questions about the definition of death, the prolongation of life, the availability of voluntary abortion, and other moral concerns. Neither social nor value-oriented humanism proposes a scientific study of these issues in order to understand the psychological and sociological implications of the present state of affairs. In our opinion, change in the medical curriculum awaits a scientific study of man in relation to technological medicine and society. This mixture of science and humanism combines the systematic, deductive orientation of science to the data it studies with the compassionate, empathetic, experiential focus of humanism. It is from study, in these terms, of the present human condition that we can redefine the role of the physician in relation to the society that he serves.

THE EXPERIENTIAL IMPACT OF MEDICAL EDUCATION

Our medical schools make overwhelming and inhuman demands. Issues of life and death are presented to the student with a minimum of preparation and with no opportunity for him to explore his human reactions to these basic human experiences. There appears to be a one-to-one correspondence between those issues the physician is not prepared to discuss with his patients and the psychic shocks the student has been left to deal with—cadavers on the dissection tables and death at the bedside, sexuality in the student's marriage and in the physician's consulting room, the fear of death in the student's patient in physical diagnosis and in the physician's patient when he discovers a fatal disease, feelings suppressed by the student in competition with other students and inadequately understood by the physician in practice when expressed by his patients. We prepare ourselves and our students insufficiently to meet their needs and the needs of their patients in the area of personal human experience. The most primary, pervasive, pressing, and human experiences become foreign to our students. Interpersonal closeness, accessibility of one's own feelings, integrated sexual gratification, and a realistic understanding of death are not part of the physician's personal life

armamentarium for dealing with his patients and their diseases.

Another problem in medical education somewhat related to this is the isolation of learning about human functioning and human disease from personal experience with the patient, his disease process, and its ramifications in the patient's life and the lives of those with whom he lives. The design of the medical school curriculum and the impact of modern technology pull the student away from learning about people and their diseases as a consequence of personally meaningful and interesting experiences with patients. He learns by rote, dictate, or instruction the facts of disease development. He does not have an equivalent experience of the interaction of human systems in the production of diseases.

Psychiatry in particular has been at a disadvantage in the medical school curriculum because of its separate presentation as course material distinct from the other basic medical and clinical sciences. Too many students become interested and adept in psychiatry only to leave these newly found skills for use with "psychiatric patients" when they return to their medical, pediatric, or other rotations. It has been a problem to integrate a student's learning about the psychological dimensions of patients with his appreciation of patients' physical illness and to integrate the acquisition and application of psychotherapeutic skills for nonpsychiatric patients with the acquisition and implementation of physical diagnostic and therapeutic skills.

THE RELEVANCE OF PSYCHIATRY

Psychiatry potentially offers in its body of knowledge about human behavior the opportunity to understand and interact with each of these problems. The focus of modern dynamic psychiatry on understanding in personal terms the individual's experience uniquely arms psychiatry, among all of the medical sciences, to uncover and clarify the impact of experiences during medical education on our own lives and practices. All of us would agree that the student, faced as he is by a unique and nearly overwhelming experience when he is first presented with a cadaver, a dying child, or a sexually seductive patient, would probably benefit from the opportunity to reexamine in a more reflective setting his own reactions, thought associations, and action tendencies and to reconsider his choice of behavior in terms of this more carefully thought-out review of his reactions.

Under these circumstances, traditional defenses or defensive resolutions—adopted from medical student lore, identification with faculty members, conceptions about the physician's role, or other sources—might be avoided as new options for behavior are brought into the situation and become viable choices for the student. In order for psychiatry to participate in this personal growth of students, it has to be more closely integrated into the student's medical school experience and readily available in times of crisis, as well as being an ongoing resource in the delivery and teaching of humanly oriented services.

In practical terms this means teaching the basic and clinical sciences as they impinge upon or derive from the world as experienced by the student. It also means we must pay more attention to the student as an individual and to his personal adaptation in medicine.

The functionally organized curriculum centers all the relevant basic or clinical sciences around the organ or social systems and so more closely approximates the student's experience of health and disease in himself, his family, and his present patients. Psychiatry can be usefully integrated into almost all courses that are functionally developed around the organ systems. This provides a unique opportunity for the student to grasp, in a personally integrated way, the physical and psychodynamic aspects of each of his patients' diseases.

UNIVERSITY OF CONNECTICUT UNDERGRADUATE EDUCATION PROGRAM

The University of Connecticut Health Center consists of the University of Connecticut School of Medicine and Dental Medicine. A common program for medical and dental school students during the first two years covers the basic behavioral and biological sciences under a series

of teaching committees (tables 1 and 2). The final two years are devoted to clinical training, with the opportunity for the student to select a specialized area of study and to spend as much as the last year and a half in this area. The uniqueness of the functionally organized curriculum for psychiatry is in the diversity and breadth of social-psychological and personality theories that can be presented.

Social and Behavioral Sciences, one of the first teaching committee courses in the first year, deals with the individual in relation to the family, social organization, and society at large. It provides an introduction to the interaction of man with society, with particular attention to the social behavior of health providers and health seekers. It aims to prepare the student for understanding and interacting with the health system of our society.

The Central Nervous System Subject Committee presents the final first-year course. Here individual psychopathology is studied from three perspectives: symptom recognition and descriptive diagnostic psychiatry, the dynamics operative in the major disease categories, and biological considerations in behavior, including genetics, dream research, ethology, and other concepts in biological psychiatry.

The other organ system teaching committee courses are given during the second year. The courses of the Respiratory, Cardiovascular, Gastrointestinal, and Endocrine and Reproductive Committees provide the opportunity to give the student didactic, clinical, and laboratory experience in the physiological-psychological interactions that operate in the production of disease. Duodenal ulcer, reproductive hormonal influences on mood and sexual activity, family interaction in asthma, and hypertension each provide the opportunity for a balanced presentation of relevant physical and psychological perspectives. The student's experiences in dealing with these diseases play an important part in sensitizing him to the relevance of psychological factors in physiological disease.

Growth and Development, the final course in the two-year base curriculum, studies personality from the perspective of the life cycle. The individual's growth and development are reviewed, with particular attention to the interactions of physical and psychological change and to the unfolding complexity of the developing individual.

Students pursue individual interests in electives offered throughout the first two years. Most teaching committees offer up to 20 hours of an elective, with a separate one-month elective period scheduled in each of the first two years. Each student engages in a supervised project, and tutorials with faculty members are available. An important aspect of this diversity is that it encourages the development of special interests on the part of individual students and facilitates the ongoing, in-depth, personalized contact of faculty and student as common interests are identified and explored.

The focus on interdisciplinary study is continued in the Introductory Clerkship that begins the third year. During this required three-month clinical experience, patients are worked up from both medical and psychiatric perspectives. Preceptors from internal medicine, pediatrics, and psychiatry are available and the student is encouraged to focus on the patient and to use specialized medical programs as a resource. By simultaneously assuming responsibility for the physical, psychological, and social needs of his patients, the student appreciates how overly specialized medical services can fractionate care.

TABLE 2
Psychiatric Teaching in the Curriculum

Growth and Development	23	20	1	44

*Proposed for addition to or scheduled for inclusion in curriculum as psychiatric teaching personnel become available.

ADVANTAGES OF THE FUNCTIONAL CURRICULUM

The initial reactions of our department of psychiatry to a functional curriculum were negative because of the implications in our minds of not having a separate, clearly defined psychiatry course during the first two years. Experience has changed our opinion to enthusiastic support for its advantages over traditionally organized medical education.

We found we could meet our psychiatric training objectives for undergraduates by presenting descriptive, dynamic, biological, and psychosomatic psychiatry in the courses of the various teaching committees. Using new methods of organization, we variously combined didactic, laboratory, and clinical sessions to provide a broad basic psychiatry experience for our students.

A clearly defined or identified didactic psychiatry course in the curriculum isolates this learning for the student and leaves it to him to develop his own links between psychosocial and physiological disease parameters. Too often, for medical students this has meant the neglect or rejection of the psychological, social, and experiential aspects of their lives and their patients' lives. The effective integration of psychiatry's viewpoint with those of the basic biological and clinical sciences in each of the organ system teaching committees does not emphasize psychiatry to the student as a separate discipline, nor does it center the acquisition of interpersonal skills around spe-

cific psychiatric diseases. Rather, it introduces psychiatric concepts in their natural context, as they arise in conjunction with disease in functioning human organ systems.

Through the functional curriculum we achieve an increased sensitivity in students to their own and to their patient's psychosocial experiences. The experientially learned responsiveness is actually more difficult to achieve in traditional curricula, where learning about the human experience of health and disease is fragmented and deemphasized in the basic science years and lost in the complexities and technology of specialization in clinical rotations. Of particular importance for understanding the impact of a functionally organized curriculum is the naturalness with which physiological and psychological aspects of disease can be meaningfully and directly a part of the student's basic science and clinical experience.

Teaching psychiatry in context with other medical subjects also has the advantage of distributing psychiatric teaching over all the student's basic science and introductory clinical courses during the first two and a half years. Psychiatry is not presented in a single block, with the student's attention turned full-time to the acquisition of a defined body of knowledge. Rather, the student, in his orientation to patients and to their diseases, is repetitively called upon to consider the interrelations among the patient, the disease process, and the patient's psychological functioning and personality structure. Previously introduced concepts are applied in new contexts in which their learning and mastery are reinforced by their use in analyses of varied and diverse clinical experiences.

A particularly useful device has been the establishment of time within each of the organ system teaching committees for students to pursue special areas of study. The 20- to 24-hour special clinical or laboratory project within subject committees gives psychiatry an opportunity for more individualized experiences in depth as a further basis for student growth. We have designed projects for studying response to psychotropic drugs, psychophysiological interactions in patients with duodenal ulcer, and sexual responsiveness during the menstrual cycle. These provide students the opportunity to interview numbers of patients with psychobiological disease disturbances. This broadens the student's clinical experience and provides a more diverse opportunity for the student to become aware of the ramifications of disease and its implications for patients' lives. Required research projects and elective courses in the basic science and clinical years each provide additional opportunity for students to discover and pursue areas of special interest. Commitment to teaching basic principles as they arise in the course of a student's pursuit of individual interests emphasizes active, self-guided learning and avoids the sterility of didactically transmitted information and skills.

Student response to the program has been increasingly positive. It has been particularly gratifying to find students developing strong personal interests in specific activities within the curriculum. The emphasis on creating learning opportunities in which students work directly with individual faculty members, over significant periods of time, encourages individual students to pursue more intensive study of areas of particular interest. This is reflected in the increased responsibility each student takes for his own learning.

We have discussed the participation of psychiatry in a functionally organized curriculum. Students in the program we have developed achieve adequate knowledge of areas of traditional concern. We propose that in addition they have a more general appreciation for the importance of psychological behavior in all aspects of health care, as a result of the systematic presentation of psychiatric concepts in the general medical context. This aids the student in accepting learning about psychological functioning as a natural part of his medical experience and does not reinforce the defensive resistance many students develop when psychiatric information is forced upon them in traditional didactic settings.

A Medical Interviewing Course: Objectives, Techniques, and Assessment

BY DAVID W. CLINE, M.D., AND JUDITH N. GARRARD, PH.D.

The authors describe a course for teaching medical interviewing skills to medical students. Course components included a programmed manual, observing a skilled interviewer, role-playing exercises, programmed medical interviewing films, and interviewing patients. The majority of the course was conducted in a small-group setting during a one-week period. Student participation was emphasized in course planning and discussion groups and as learners and teachers. Students and instructors rated the course as above average to excellent. The students showed a significant learning gain in medical interviewing techniques.

OVER THE PAST SEVERAL YEARS, medical interviewing skills have received increased emphasis. The focus on family practice and comprehensive medicine and the demands of the consumer that he be skillfully interviewed and be made to feel that the physician is interested in him are forces within our society which require that more training be focused upon the skill of interviewing. Teaching interviewing skills has been initiated in graduate training programs in psychiatry, clinical psychology, social work, and more recently in the undergraduate medical school curriculum. Although several formats for teaching interviewing skills have been described (1–6), course objectives, teaching techniques, and assessment of outcome (especially student-teacher satisfaction and student gains in learning) need further clarification by research.

The department of psychiatry at the University of Minnesota Medical School is responsible for teaching medical interviewing techniques to the phase B (second-year) medical students in the recently revised medical school curriculum. The purpose of this article is to describe this course, outlining course goals and components, teaching techniques, and assessments of what the students learned and their satisfaction with the course; the latter aspect has become an important one in the new student activism movement.

COURSE DESCRIPTION

An interdepartmental committee consisting of several faculty members and two first-year medical students planned the course. The first step in course development was to specify the body of information to be presented. The optimal interview was defined as one in which the greatest amount of accurate information relevant to diagnosis and management was obtained in realistic time limits (2). The course goals were as follows: 1) to increase the student's attention to process information; 2) to encourage techniques that maximize the opportunity for observing the patient's characteristic behavior; 3) to encourage the interviewer to limit his own activity and to encourage the patient's activity; 4) to encourage the interviewer to exercise the least possible control over the patient; 5) to encourage the interviewer to allow the patient to tell his own story with minimal intervention; and 6) to encourage the interviewer to create and maintain a supportive emotional atmosphere. The course was given during a one-week period at the beginning of the second year of medical school, before the students performed medical workups. There were 12 hours of required attendance and six hours of optional attendance.

During the first hour (required) of the course, a pretest was administered to the class (N = 233) in a large-group setting. The quiz, in the form of two films, depicted interviews with white, middle-class, male patients in whom carcinoma was suspected. The test had 18 nodal points, with three alternatives at each point from which the student chose one response. These test films were part of the series "Programmed Instruction in Medical Interviewing" done by Enelow and associates (7), and their purpose was to test cognitive learning (8). Also included during the first hour were a general introduction to interviewing techniques, the reading assignment, and course goals and format.

Medical Interviewing: A Programmed Text (6) was the required text, which students were to read at the beginning of the course. This manual focuses on the format, style, and phrasing of questions and responses to fit the many types of situations that occur in interviews. Approximately 20 types of responses are defined, illustrated, and programmed (e.g., facilitation, confrontation, silence, open-ended questioning, support, reassurance, empathy, and reflection); from these the student can learn to construct his own responses of each type.

The major portion of the course was taught in a small-group setting (eight to 14 students), led by an instructor from psychiatry, psychology, or social work. During the first of five required two-hour blocks, the instructor demonstrated interviewing techniques by interviewing a hospitalized patient. The interview, which was audiotaped, lasted about 25 minutes and was followed by students asking the patient open-ended and direct questions. The group then discussed the interview, and the patient participated by reporting his reactions to the experience. In this setting the students observed a skilled interviewer; the patient's presence served to decathect the anxiety surrounding the interviewing experience.

Two small-group sessions that followed were devoted to role playing. Each student was asked to learn a patient's history, and then a fellow student interviewed him. Subsequent reversal of roles allowed the student to experience the interviewing process as a "patient," gaining greater appreciation of the importance of the interview. The instructor could also interview a programmed "patient," further demonstrating effective techniques and dispelling the notion that role playing is ineffectual as a learning tool. Audiotape recordings were used as a teaching aid to point out students' errors.

The final two small-group sessions were devoted to students interviewing hospitalized patients. Two students—one an interviewer, the other an observer-recorder—went to a hospital station and interviewed a patient for approximately 20 to 30 minutes; the interview was audiotaped. Following the interview, students returned to their small groups where the student observer-recorder critiqued the interview. The instructor used the audiotape recording to provide critical feedback to the student-interviewer. Interviewer-observer roles were subsequently

The authors are with the University of Minnesota Medical School, 412 Union St., S.E., Mayo Box 393, Mayo Memorial Building, Minneapolis, Minn. 55455, where Dr. Cline is Assistant Professor, Department of Psychiatry, and Dr. Garrard is Medical School Curriculum Evaluator and Assistant Professor, Department of Physical Medicine and Rehabilitation.

The evaluation and statistical analyses were supported by Health Professions Special Project Grant Program grant ME-00109 from the National Institutes of Health.

TABLE 1
Student-Instructor Evaluation

Area	Student Ratings (in Percentages)			Mean Ratings	
	Excellent or Above Average	Average	Below Average or Poor	Students	Instructors
Course Goals: Rate how well you feel you (your students) accomplished each goal in this course.					
1. To increase the student's attention to process information	83	14	3	1.80	1.57
2. To encourage observation of the patient's characteristic behavior	81	17	3	1.85	2.12
3. To encourage the interviewer to limit his own activity and encourage activity on the part of the patient	88	11	2	1.69	2.05
4. To encourage the interviewer to exercise the least possible control over the patient during the interview	76	19	5	2.00	2.24
5. To encourage the interviewer to allow the patient to tell his own story with minimal intervention	85	12	2	1.71	1.81
6. To encourage the interviewer to create and maintain a supportive emotional atmosphere during the diagnostic interview	80	21	0	1.84	1.81
Instructor or Self-Evaluation: Rate how effective your instructor was in helping you accomplish the goals of this course (your effectiveness as an instructor)	91	6	3	1.54	1.98
Course Components: Rate the effectiveness of each of the following course components in helping you (your students) accomplish the goals of this course.					
1. "Programmed Instruction in Medical Interviewing" films	58	30	11	2.44	3.08
2. Demonstration interview of a patient by group leader	77	17	6	1.97	2.45
3. Student interview of a student role-playing a patient	68	23	9	2.13	2.24
4. Student role-playing a patient being interviewed	55	30	14	2.41	2.20
5. Student interviewing a patient	90	8	2	1.44	1.83
6. Student observing a fellow student interview a patient	81	19	1	1.76	2.33
7. Pre-post exams	30	41	30	3.08	3.00
8. Required text "Medical Interviewing: A Programmed Manual"	46	31	24	2.75	—
General: Rate the interviewing course in general.	90	7	3	1.63	—

reversed. This presented a unique opportunity for the student to be an observer-teacher, thereby enhancing his own learning.

Following each of the required small-group sessions throughout the week, interviewing movies (7) were presented in a large-group setting to enhance the learning of both verbal and nonverbal aspects of patients' responses (attendance optional). Ten programmed interviews, available on videotape and on 16 mm. film,[1] were written to illustrate specific interviewing problems and techniques (8). Professional actors played the roles of patient and physician. At certain nodal points the student chose among three alternate physician responses rather than constructing his own response. This format allowed the student to become actively involved with the more complete verbal and nonverbal responses of the physician and replies of the patient. The film narrator's commentary about each type of response added to the student's understanding of the process. The films were supplemented by class discussion following the completion of each.

A posttest, consisting of showing the two pretest films, was administered in the large-group setting during the final required hour of the course. The student was given his pretest and posttest scores and the class average so that he could further assess his learning gain.

COURSE ASSESSMENT

In order to assess the educational value of this course, an extensive evaluation was conducted. The students (N = 233) were asked to rate their own and the instructors (N = 21) were asked to rate the students' accomplishment of the course goals, effectiveness of the course components in accomplishing these goals, instructor effectiveness (for the instructors this was a self-evaluation), and the overall value of the course. The following rating

[1] The ten interviewing films and two test films are available on request from the National Medical Audio-Visual Center (Annex), Station K, National Institutes of Health, Atlanta, Ga. 30324.

schedule was used: 1 = excellent, 2 = above average, 3 = average, 4 = below average, and 5 = poor. Of the group, 216 students (92 percent) and 21 course instructors (100 percent) responded to the questionnaire. Cognitive learning gain was evaluated by pre- and posttest comparisons.

The group leaders consisted of four staff psychiatrists, three staff psychologists, ten psychiatric residents (who had completed their first year of training), two staff physicians from the department of family practice and community health, and two staff social workers. Seven of the 21 group leaders had been instructors in the course the previous year, the first time that it was offered. Most of the 14 remaining group leaders had had no formalized course work in interviewing techniques during their specialty training, although all group leaders were given instructional kits and were invited to attend an instructional seminar before the course began.

RESULTS

Of the students, 77 percent had had no previous training in interviewing techniques; 14 percent had had some training in an elective course offered the previous quarter; and 9 percent had had previous training with other groups. None of the students had had previous experience conducting medical interviews with patients. Eighty-five percent of the class attended all required and optional sessions of the course.

Table 1 shows the distribution of ratings (scores 1–5) and mean ratings obtained from the student and instructor evaluations.

Students rated the course between "above average" and "excellent" (mean rating = 1.63). In rating their accomplishment of each course goal, the students assigned the highest mean rating (1.69) to goal 3—"to encourage the interviewer to limit his own activity and encourage activity on the part of the patient." The course component that the students found most effective in learning interviewing techniques was their interviewing a hospitalized patient (mean rating = 1.44). The instructors felt that, of the course goals, goal 1 was best obtained by the students: "to increase the student's attention to process information." This goal was rated third highest by the students. The course component ranked highest by *both* students and instructors was "student interviewing a patient"; this and the subsequent small-group discussion were apparently the most important elements in teaching and learning interviewing techniques.

Comments by the students included: "Excellent course." "Need to interview more real patients." "Course should be longer with periodic follow-up." "Our small-group experience was excellent." "More case history role playing." "Most valuable part of my experience was self-evaluation tempered by fellow students' empathy and critiques." "Feel that a videotape interview and playback should be required for all students."

Regarding the social work instructors: "Destroyed my own distrust of social workers." "She suffered typical medical student wrath for a non-M.D.—handled it very well."

About the text: "Not worth buying, especially for $5, not worth it." "Good." "No good." "Bad book."

About the films: "Somewhat of a comedy." "One or two films sufficient." "Went to sleep; yes, I went to bed the night before."

The course in general: "A very excellent experience."

Comments by the instructors included: "Good to let students interview their fellow students, role-playing a patient first, which helps them to get the feel of interviewing while under minimal stress." "It was a rewarding experience to teach the course."

TABLE 2

Mean Number Correct and Mean Weighted Scores for Second-Year Medical Students (N = 207)

Item	Pretest	Posttest	Level of Significance
Film 11 (Mr. King)			
Number correct*	6.04	7.97	$p<.001$
Weighted score**	13.09	16.29	$p<.001$
Film 12 (Mr. Lloyd)			
Number correct*	4.86	7.09	$p<.001$
Weighted score**	12.61	15.66	$p<.001$

*Maximum number correct = 9.00.
**Maximum weighted score = 18.00.

LEARNING GAIN

Cognitive learning of interviewing skills was assessed by two test films designed by Adler and associates (8); both films were administered before and after the course. Each film contained nine nodal or decision points. At each nodal point, an interview situation was portrayed, followed by three alternative physician responses. The student had to decide which alternative was appropriate and record this on his answer sheet. The nodal points within and between films were designed to be independent of one another; therefore, a student's answer at one point should not influence his subsequent responses.

In order to control for possible sequence effect, the order of the films was alternated on pre- and posttest. That is, for the pretest, Film 11 (Mr. King) was shown first, followed immediately by Film 12 (Mr. Lloyd); the order was reversed for the posttest.

Complete pre-post data were obtained for 207 students (85 percent); the results are shown in table 2. The mean number correct and mean weighted scores (8, p.16) are given for each film.

On the basis of a matched-pairs t test significant pre-post differences ($p<.001$) were found with each film; these differences were evident regardless of whether number correct or weighted scores was the dependent variable.

In order to examine the extent to which the two films

were parallel, a Pearson correlation coefficient was run with the pretest scores. The correlation (r_{xy} = .34) was the same for number correct and weighted scores.

DISCUSSION

The significant differences between the pre- and posttest scores were interpreted as an indication of significant learning gain attributed to the one-week course.

Weighted scores were derived originally (8) in order to make the two test films parallel. In previous research Adler and associates (8) reported correlations for weighted scores ranging from .49 to .69 for various groups of academic or practicing physicians. Although Adler and associates assessed second-year students at two medical schools (N = 61 and N = 75), their test administration did not include both films; therefore, correlations between the films were not available. The results of the current study do not offer strong support for the assumption that use of the two films will provide parallel results for sophomore medical students; therefore, the use of one film as a pretest and the other as a posttest cannot be strongly justified for second-year students.

A major consideration in presenting this course was faculty time required to teach interviewing skills. Excluding preparation, the 21 instructors each spent ten hours teaching during one week, for a total of 210 teaching hours for the class of 233 students. The course director spent six hours presenting the films, discussing them, and administering the pre- and posttests. He spent additional time organizing the course, scheduling, recruiting group leaders and patients, and obtaining tape recorders, as well as supervising the course presentation.

Presenting the course in a one-week time block facilitated maximum participation by the group leaders. Interest, morale, and enthusiasm were more easily maintained than if the course had been spread over several weeks. It is important, however, to reinforce the concepts presented in the course at periodic intervals throughout the medical students' training. However, Ware and associates (9) have shown that learning gain persists six weeks after the presentation of the programmed instruction films (7) over a previous ten-week period.

Videotaping student interviews and playing them back appears to be a valuable teaching adjunct (1), although Adler and associates (4) reported that "Programmed Instruction in Medical Interviewing" films (7) were superior to videotaped interviews and discussion in producing certain behavioral changes that were measured by the Psychotherapy Interactional (PIA) Scale (10). We are currently studying the value of including the videotape learning experience. Initial problems for large medical school classes are the availability of equipment and technicians to operate the equipment, and scheduling instructors, students, patients, and/or a programmed patient. Logistical problems are pronounced.

Using a professionally trained programmed patient has value in that the "patient" is available for comments during the review session, clarifying interpretations of the student's response or why he replied as he did to a specific inquiry. However, this duplicates somewhat our practice of having a fellow student role-play the patient. Since the student patients can quickly be taught to provide feedback to their colleagues and since using student patients greatly reduces logistical problems, this approach seems to be the most expedient.

Teaching Communication Skills in Medical School

BY JOHN WALDRON, M.D.

The author describes a method for teaching a communication skill (interviewing) to medical undergraduates. In addition to the use of closed-circuit television, feedback from instructors and peers was encouraged. The author outlines students' reactions to this technique and discusses conclusions drawn from four years of using it.

THE FOLLOWING PAPER PRESENTS a description and discussion of four years' experience in developing methods for teaching communication skills to medical students in the department of psychiatry at Queen's Medical School in Kingston, Ontario.

First, it seems appropriate to comment on definitions. A number of professions have acquired skill in communications in order to conduct work properly. In several of these professions (e.g., journalism and television) the ability to communicate often implies the capacity to transmit information accurately. In recent years such skills have been emphasized in some programs involving aspects of preventive medicine (1). However, in the medical and helping professions, communication generally is, or should be, given its full meaning as an *exchange of information* between two or more people. It is consequently at the heart of the patient-doctor relationship and is emphasized as such in curricula devoted to this area.

In its best recognized form communication entails the capacity to listen to the patient, not in a passive manner but while employing judiciously spaced and phrased questions and indications of encouragement and understanding designed to elicit a valid account of the patient's troubles. This describes the medical interview or perhaps more precisely the diagnostic medical interview.

In the past a great deal of confusion has been generated by the different uses of the terms "interview" and "history taking." We have discussed some of these problems elsewhere (2). Most of the work with medical undergraduates at Queen's University has been predicated on the view that there is no essential difference between these procedures (3). We particularly do not feel that interviewing should be identified as a psychiatric skill to be taught only by psychiatrists but, rather, that all clinical teachers should recognize as their responsibility the demonstration of proper interviewing or communications skills in the service of eliciting a proper history from the patient.

Dr. Waldron is Associate Professor of Psychiatry and Associate Dean, Faculty of Medicine, Queen's University, Kingston, Ont., Canada.

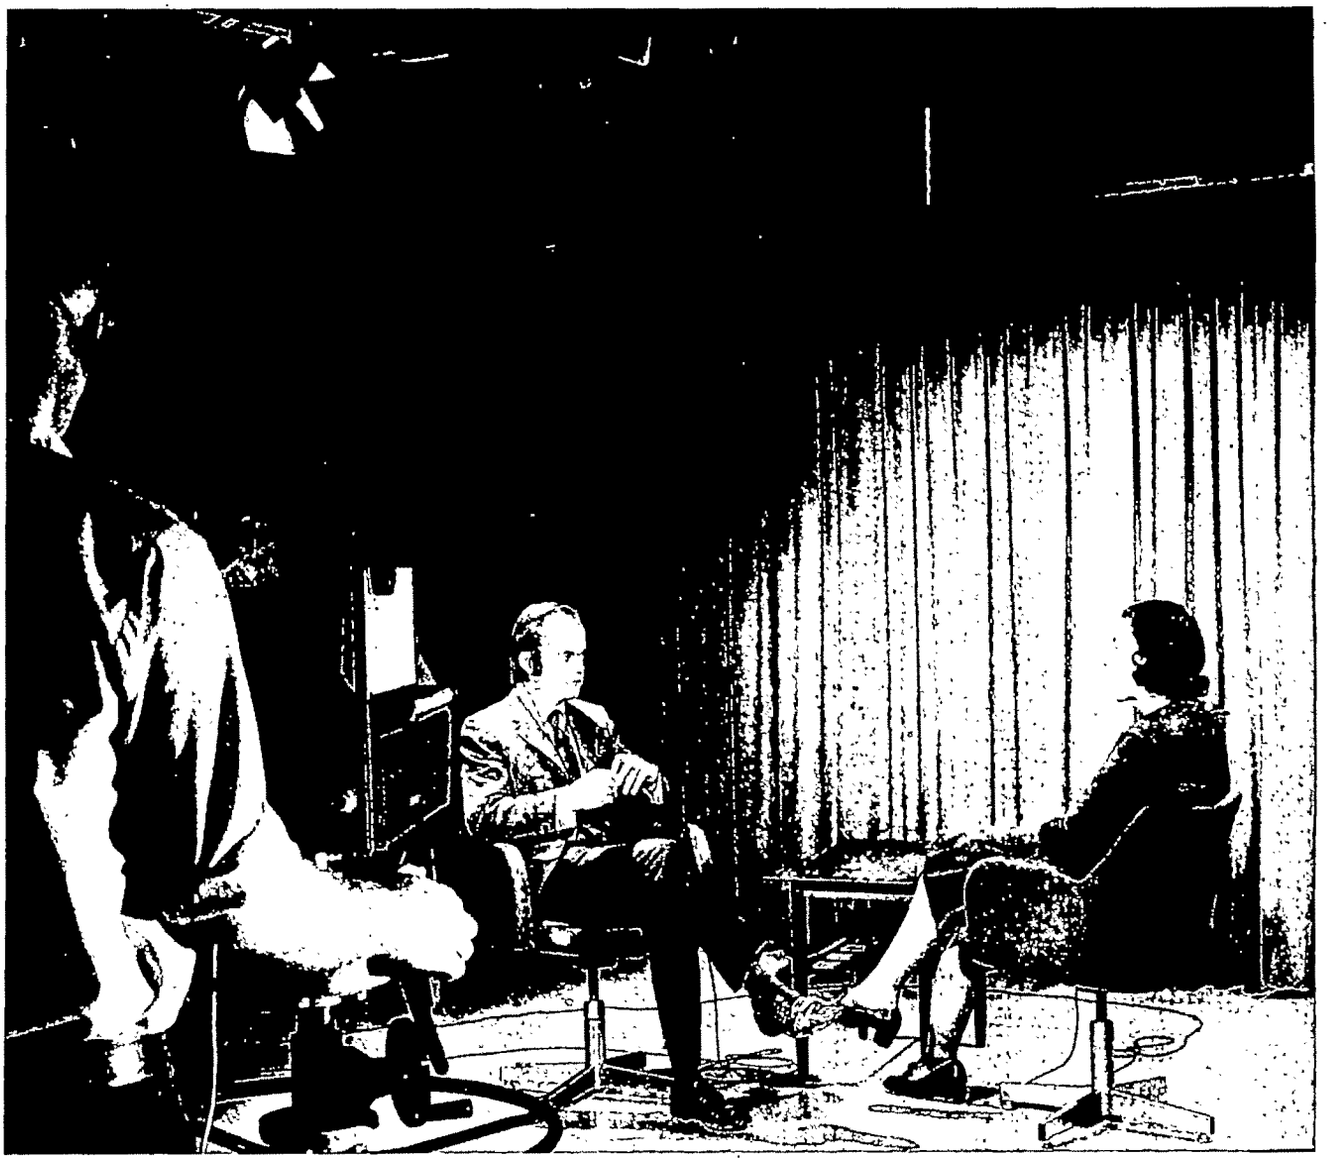
The author wishes to thank Ms. Beverley Lazier and the staff at Queen's Closed-Circuit Television for their assistance and encouragement.

DESCRIETION OF TECHNIQUE

The principal component assisting our method over the last four years has been closed-circuit television, a technique described by several other workers (4, 5). The facilities available to us, which were quite sophisticated, were located in the university's television center. We later demonstrated that our techniques did not suffer when we used modest portable equipment.

Though employing elaborate equipment at times, we have at no time employed any kind of disguise. We had earlier resolved that a vital ingredient in the doctor-patient encounter was honesty, and we were therefore not inclined to give the lie to our stated principle by staging a "let's-play-doctor" game. The exercise was conducted for what it was—a medical student learning his job by conducting an interview with the patient, who was fully aware of all the circumstances, including the clearly visible equipment (see figure 1).

The details of our technique follow:



1. The students, who undertake this course in their third year of medical school, have already witnessed demonstrations of interviewing styles in their second year. They have also been given specially prepared handouts designed to inform them about some of the basic maneuvers in talking with patients.

2. The students rotate through psychiatry for eight weeks, during which time they meet once a week in small groups of three or four participants to study interviewing techniques. Each student is given two opportunities to conduct a 40-minute diagnostic interview with a patient. He is instructed to do this so that by the end of the interview he is in a position to make a tentative diagnosis, discuss the prognosis, and report on the patient's mental status.

3. This interview is videotaped, as described previously, and at the same time monitored by the tutor and the remaining two or three peers in the student group. During the recording, the tutor uses the student's ongoing performance to teach the other group members and makes notes on the performance. Instead of referring to a specific incident during the interview, the tutor jots down for easy reference the corresponding numbers appearing in the lower right-hand corner of the screen (see figure 2).

4. Following completion of the interview, the student rejoins the group. When it is deemed suitable, the tutor

FIGURE 1*
Student Interviewing Patient

*Those appearing in the photographs are models.

may ask the patient to join the first part of the discussion to give his impressions of the student's performance. Maximum use is made of peer teaching, with the tutor joining in the discussion and making free use of videotape playback and the screen counter for accurate pinpointing.

5. After the group discussion has ended, the student-interviewer sets up an appointment with the television studio to view his performance either alone or with his group members during their independent study time. To help him, the tutor composes a written critique of the interview, again using the screen counter so the student can coordinate given incidents with the comments.

6. For a number of years we have been attempting to develop an interview rating scale with which we would pass on to the students, in as succinct a way as possible, relevant and valid information concerning their performance. Preliminary work on this scale is encouraging (2), and while we are using it at the moment as a research instrument, we hope to experiment with it as a teaching/learning device shortly.

RESULTS

While we have been developing methods, we have also been attempting to develop instruments and criteria (2).

FIGURE 2
Video Picture of Patient and Screen Counter

We do not at this time have measurements of the effectiveness of the method using our rating scales, but the course has stood up well in what we consider the most rigorous test of any educational method—the constant and enthusiastic reception from the students involved. The only consistent criticism the students have offered is that such teaching methods should be employed in the first year of the curriculum rather than in the third.

DISCUSSION

We have made a number of conclusions as a result of our experience with this course over the last four years.

The first and most obvious is that skills of this kind not only should be but can be taught at the earliest possible time in medical school. In this we agree with the students. There is little to support the classical contention that before one commences to learn these skills one must first have acquired a considerable amount of knowledge from lengthy lectures given by the teacher. We feel that we can safely assume that most medical students bring to school sufficient knowledge and skill in the area of communication to permit the commencement of teaching in this area very early in medical school.

Second, we have concluded that complete honesty in the student-patient encounter is necessary. As we anticipated, the openness of our techniques and the absence of disguises generated, with few exceptions, what we felt was a genuine existential encounter that was of value to both the patient and the doctor. We feel that this is an important observation in view of the hesitancy of many teachers and students to become involved in what they see as an artificial and theatrical procedure.

The third observation, and one that is well-documented in the literature (6), is that the experience of viewing oneself in replay is probably the single most important learning experience for the student. Students have repeatedly told us that the tutors' written and spoken comments were hardly necessary to point up their errors since they were painfully evident when viewed on the television screen.

Evaluation of the SAID Teaching Program

BY DAVID W. CLINE, M.D., AND JUDITH N. GARRARD, PH.D.

Evaluation of a new teaching program suggests that second-year medical students can be taught psychiatry with a multimedia combination of filmed interviews with patients, an inventory of critical symptoms, a diagnostic chart illustrating clustering of symptoms for basic diagnosis, and rapid feedback of faculty evaluation. When compared with controls, experimental subjects did significantly better in evaluating filmed patients, but there was only a trend that they did better when evaluating psychiatric patients at the bedside. The students rated this program as an effective teaching approach.

MILLER AND TUPIN (1) have recently published a description of the System Analysis Index for Diagnosis (SAID), which is a method to teach clinical psychopathology to second-year medical students and other mental health professionals. The SAID system is a multimedia teaching device that emphasizes student participation in a structured psychiatric patient evaluation with rapid feedback of faculty evaluation to enhance consensual validation of student with student and of student with professional.

The system operates as follows: The student group observes a film or videotape of a physician interviewing a psychiatric patient. Each student then makes decisions as to the absence or intensity of 40 psychiatric symptoms that are listed and defined in the *SAID Handbook* (2). With the use of a diagnostic flow chart, he is directed to pool the symptoms recognized to construct a likely psychiatric diagnosis. For example, the student would have had to evaluate the psychiatric patient as having a mild degree of impaired intellectual capacity, disorientation-memory loss, and disordered attention-consciousness in order to make a likely diagnosis of nonpsychotic organic brain syndrome. For the diagnosis of psychotic brain syndrome, he would have had to observe, in addition, the moderate presence of delusions, hallucinations, illusions, or suspiciousness.

Upon completion of his evaluation the student is given the collective faculty evaluation of the patient, including symptom absence or intensity, diagnosis, and the evidence for each of the ratings, i.e., for marked disorientation, "Patient did not remember date, day of the week, or where he was presently residing." After each videotaped exercise there is a discussion of the nature of psychopathology observed, followed by a lecture on that particular psychiatric disorder.

The student evaluation, which is marked on a computerized answer sheet, is rapidly scored and returned to him with a print-out of how his evaluation compared with that by fellow students and by the faculty. As he proceeds through the program and evaluates more patients, he can trace the changes in his clinical judgment.

The teaching strategy is to maintain optimal interest level and active involvement arousal through the use of individual participation in a simulated situation and rapid feedback.

The purpose of this research is to investigate the efficacy of this teaching method. The hypotheses are as follows. Students taught with the SAID method do better than controls in:

1. Learning skills in psychiatric symptom recognition.
2. Learning skills in assessing intensity of psychiatric symptoms.
3. Learning to make psychiatric diagnoses by pooling symptom clusters.
4. Learning content about the psychiatric disorders.

Finally, do students appraise this method of teaching differently than other methods of teaching?

METHOD

At the University of Minnesota Medical School the second-year medical students (N=230) were taught a course in clinical psychopathology during a two-week, 45-hour block of instruction in March 1972.

The major objectives of this course were to teach the students and expect them to learn: 1) about the psychiatric disorders (brain dysfunction, functional psychosis, personality disorder, neurosis, special symptomatic syndromes, and behavioral disorders of childhood and adolescence), 2) about psychiatric symptom recognition, 3) to accurately evaluate intensity of psychiatric symptoms, 4) to organize psychiatric symptom clusters together to make a psychiatric diagnosis, 5) about psychiatric treatments, and 6) about mental health treatment resources.

The methods of teaching involved multimedia team teaching, as described in the SAID method above. Table 1 describes the time distribution of the instruction period.

Read at a panel at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1-5, 1972.

The authors are with the University of Minnesota Medical School, 412 Union St., S.E., Mayo Box 393, Mayo Memorial Building, Minneapolis, Minn. 55455, where Dr. Cline is Assistant Professor, Department of Psychiatry, and Dr. Garrard is Medical School Curriculum Evaluator and Assistant Professor, Department of Physical Medicine and Rehabilitation.

The work for the statistical analyses was supported by Health Professions Special Project Grant Program grant ME-00109 from the National Institutes of Health.

TABLE 1
Topic Hour Distribution

Topic	Hours
Classroom	
Overview and mental health treatment resources	2
Problems of childhood and adolescence	9
Organic brain syndromes	4
Schizophrenia	3
Affective disorders	4
Neurosis	3
Suicide	1
Drug and alcohol abuse	5
Personality disorders	2
Total classroom hours*	33
Tutorial	8
Precourse and postcourse tests and feedback	4
Total	45

*SAID videotapes with feedback discussion accounted for ten of these hours.

In addition to the SAID system, each student was required to evaluate a psychiatric patient in a real-life setting under the tutelage of a faculty psychiatrist. The purpose of the tutorial was that the student: 1) recognize the nature and intensity of the psychiatric symptoms presented by the patient, 2) organize symptom clusters together to make psychiatric diagnoses, and 3) suggest possibilities for treatment for the patient. The tutorial was conducted near the end of the 45-hour block of instruction, after the SAID films and lectures were completed.

STUDY SAMPLE

Sixty students were randomly selected from the 230 members of the second-year (phase B) medical school class and assigned to either an experimental (E) or control (C) group. Students in the C group (N=30) were asked not to attend the SAID videotape-feedback-discussion sessions (ten hours of the course) and instead to use the time for independent study. Otherwise, they were to attend the lectures, the live patient demonstration, the tutorial, and the precourse and postcourse examinations. Students in the E group (N=30) were asked to attend all of the course's core presentations described above.

MEASUREMENT INSTRUMENTS

During the first and last hours of the course, a two-part examination was given. Part 1 was a ten-minute videotape showing a physician interview with a patient who had a psychiatric disorder. The students were asked to list the psychiatric symptoms they observed, the psychiatric diagnoses, and then collate the symptoms with each diagnosis. Part 2 was a true-false examination consisting of 78 questions about the psychiatric disorders. Although the pretest and posttest were of the same format, they contained different patients and questions. Both tests were designed by Paul R. Miller (2).

A second method of assessment was by tutor ratings. Prior to the beginning of the course, each tutor was assigned one student from each group (E and C). All tutors (N=30) participating in this study were members of the psychiatry department. They were not told of the difference between E and C students.

During the tutorial, each student evaluated a different psychiatric patient and reported his findings to the tutor. Using a standard rating form, tutors rated students on the basis of: 1) recognition of different kinds of psychiatric symptoms, 2) correct identification of intensity of symptoms, 3) correct diagnosis, 4) knowledge of appropriate treatment, and 5) general performance. A rating scale of 0 (poor) to 100 (excellent) was used with the first three areas rated, and a scale of 1 (excellent) to 5 (poor) was used with the last two areas.

A final measure was a student evaluation of the course. This consisted of a questionnaire asking the students to rate the various components of the course results.

RESULTS

Tables 2–4 show the results of the precourse and postcourse examinations for groups E and C, the results of the tutor evaluation of E and C subjects, and the results of the student evaluation.

Do students taught with the SAID method do better than controls in:

1. Learning skills in psychiatric symptom recognition?

TABLE 2
Pretest and Posttest Scores Comparing Groups E and C

Item	Group	Number*	Pretest Mean	Posttest Mean	Value of T	Level of Significance
Filmed patient evaluation	E	28	13.0±2.5	17.1±2.8	4.550	p<.001
	C	28	13.0±2.6	14.0±2.6	.015	n.s.
True-false examination	E	17	46.2±5.0	59.1±4.0	3.002	p<.001
	C	20	51.3±3.7	59.5±4.6	2.053	p<.01

*Number varies depending on students' completion of both pretest and posttest and proper identification of test answer sheets.

TABLE 3
Tutor Evaluation of Group E and C Subjects (N=20 Pairs)*

Item	Group E Mean	Group C Mean	Value of T	Level of Significance
1. Recognition of the different kinds of psychiatric symptoms**	65.5 ±15.4	63.5 ±21.6	.3393	n.s.
2. Correct identification of the intensity of psychiatric symptoms**	67.7 ±14.5	62.5 ±18.3	1.0995	n.s.
3. Correct diagnosis of the patient's problems**	56.0 ±20.7	67.5 ±19.4	.2360	n.s.
4. Knowledge of appropriate treatment***	2.55± 0.69	2.85± 0.81	- .4204	n.s.
5. Student's general performance***	2.25± 0.72	2.55± 0.94	1.1132	n.s.

*Of the 30 pairs of subjects, ten were eliminated because one of the members did not go to the tutorial, did not go to the first tutorial, or had previously had significantly more structured psychiatric training than his partner.
**Based on a scale of 0 to 100, with 100 as the best score.
***Based on a scale of 1 to 5, with 1 as the best score.

Results from table 2 show that on the pretest and posttest, students in group E had a statistically significant learning gain in recognizing psychiatric symptoms that they saw in filmed psychiatric patients, whereas group C students did not. However, the difference was less clear as judged by the tutors (see table 3, number 1). When real patients were used, E tended to do better, but the difference between E and C did not achieve statistical significance.

2. Learning skills in assessing intensity of psychiatric symptoms?

The results of the tutor evaluations showed a tendency for group E to assess intensity of symptoms better than group C, although the difference did not achieve statistical significance (see table 3, number 2).

3. Learning to make psychiatric diagnosis by pooling symptom clusters?

Results of the precourse and postcourse examinations indicated that group E was better able to pool symptom clusters and make psychiatric diagnoses than was group C. However, when groups E and C evaluated psychiatric patients on the ward there was no statistical difference, although group E tended to do better (see table 3, number 3).

4. Learning content of psychiatric disorder?

Both group E and group C made statistically significant learning gains regarding content material as shown by the precourse and postcourse true-false examination

TABLE 4
Student Evaluation of the Course (N=230)

Item	Ratings, in Percentages: Excellent or Above Average (1–2)	Average (3)	Below Average or Poor (4–5)	Did Not Attend (Percentage)	Average Rating
1. Overall rating. In general, how would you rate (1–5) this phase B course?	58	35	7	0	2.39
2. How intellectually stimulating was this course for you?	61	31	7	0	2.34
3. Course objectives. Rate (1–5) the extent to which *you* feel you accomplished these course objectives:					
To learn about psychiatric disorders	55	38	8	0	2.45
To recognize psychiatric symptoms	72	24	5	0	2.13
To organize psychiatric symptom clusters together to make a psychiatric diagnosis	44	44	11	0	2.60
To learn about psychiatric treatments	31	50	21	0	2.88
To learn about mental health treatment resources	14	55	31	0	3.18
4. SAID system. Rate the effectiveness of the SAID system as a method of learning symptom recognition and diagnosis in this course.	74	19	7	14	2.10
5. Lecture evaluation. Mean rating for 12 lectures.	50	35	16	6	2.54
6. Tutorial. How would you rate (1–5) your tutorials as a *learning experience* in this course?	88	8	3	3	1.59
7. Optional activities. Rate (1–5) each of the optional activities as a *learning experience*.					
Field trip to St. Peter State Hospital	39	41	21	67	2.70
Electroshock therapy demonstration	74	25	1	45	2.01
Psychiatry and the theater	82	13	5	45	1.79

(table 2). This portion of the course was taught by didactic lecture and live case presentation that all students, both E and C, attended.

Do students appraise the SAID method of teaching differently than other methods of teaching?

The SAID system was rated as above average or excellent by 74 percent of the class (table 4). The effectiveness of the lecturers, in combination with a few live case demonstrations, was rated by 50 percent of the class as above average or excellent. The average rating for these lecture presentations was 2.54 (between average and above average), compared with 2.10 (above average) for the SAID system. However, the tutorial experience was rated highest of the learning experiences, i.e., 88 percent rated it as above average or excellent, with a mean rating of 1.59 (between excellent and above average). General comments about the SAID system were, "This was very helpful." "Excellent definition of terms, but too easy to pigeonhole patients." "Liked it a lot." "Great for symptoms, still have trouble with diagnosis." "I did not like adding up numbers to arrive at a diagnosis. Seemed too simplistic to me."

DISCUSSION

The most striking finding in this study are those results which compare subjects' ability to evaluate filmed patients with their ability to evaluate real-life psychiatric patients. Although group E students were able to recognize symptoms and diagnose filmed patients significantly better than group C students, there was only a trend in that direction when they evaluated live patients.

On the basis of these results, the question becomes: What was lacking in the SAID system that did not produce significantly different results in the face-to-face evaluation? E and C students were given patients to evaluate in their first tutorial experience so that if there were differences in their clinical abilities it could be clearly shown at that time, rather than at a later tutorial experience. We could postulate that the real patient experience is so different from the classroom experience that knowledge gained from the classroom experience is not immediately transferable to the bedside. In the bedside setting the student is participating with the patient, and not only do interview techniques become important, but the art of personally eliciting psychiatric symptoms becomes important, a task not specifically addressed in the SAID system.

Miller has revised the *SAID Handbook* (2) and the SAID patient presentations on film so that a clearer model is presented to aid the student in recognizing psychopathological symptoms. For example, in the revised edition, under each symptom listed in the handbook specific questions and observations are listed, which are useful in determining the presence and intensity of the symptom. When patients are presented on film, note is made on the film of which area of inquiry is being investigated, e.g., under disorientation-memory loss, there are questions such as, "What day is it?" "How old are you?" "Where are you now?"

Another important feature of this study reveals that the SAID system is well accepted as an effective teaching tool by the students. It was easily taught to a class of 230 students. The multimedia SAID teaching system is consistent with the new trends in medical education: Its content is core curriculum, it is patient-centered, and it prepares the student directly for subsequent clinical experience. It incorporates the application of learning theory by making the student an active participant in his learning, giving him immediate frequent feedback as to how he compared with his peers and teachers. This is a major step in enhancing the teaching of psychiatry in the medical school curriculum.

Although the students rated the SAID approach better than lecture-live patient demonstration but not as good as the tutorial experience, it is important to note that a variety of teaching approaches are useful in facilitating students' learning.

EDITORIAL

Psychiatry in Undergraduate Medical Education

AMERICAN MEDICINE is in a period of change. After the publication of the Flexner report, medicine added the scientific tradition to its core identification with the role of physician and healer. As a result we have expanded our health capabilities with the elaboration of new technologies for the investigation and treatment of disease. Today medicine is being pressed to add a commitment to social change to the established roles of healer and scientist. We are struggling to assimilate the technology of health while facing the issues of health care delivery, financing of health services, citizen participation in health planning, and organization or coordination of health with other social and welfare services.

In the last three-quarters of a century the scientific study of personality has generated a theoretical and clinical dynamic psychiatry. The adaptation of the individual to states of health and illness is subject to investigation, understanding, and modification. But unfortunately the elaboration of psychiatry as a specialty has not brought modern scientific psychiatry any closer to general medicine. This is reflected in the traditional curricula for medical students. Psychiatry is presented as a series of separate courses and clerkships. The prospective physician rarely sees the psychiatrist on medical, surgical, pediatric, or other inpatient and outpatient services.

The strength of the identification as a healer, the contributions of scientific medicine, and the social benefits achieved by specialization have stabilized American medicine for more than 50 years. That stability is now threatened by forces operating within the system itself and by social discontent about the gains that have been realized when they are compared with the benefits that were expected.

Where psychiatry goes in relation to general medicine will be strongly influenced by the direction general medicine takes. General medicine is undecided about the balance between scientific technology and humanism, or between patient care and social action. Psychiatry will more constructively influence the coming social evolution of medicine if the gap between general medicine and psychiatry is closed. Each of the other options available to psychiatry has serious flaws. The traditional position of psychoanalysis is too isolated from the bulk of medicine to influence nonpsychiatric physicians. The community mental health movement substitutes consultation for direct patient contact, social action for psychological insight, and brief, economical treatment for intensive, curative insight therapy. It neglects the individual for the greater social good and thereby departs from the bedside tradition of clinical medicine. Bio-

In this section, the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

logical psychiatry uses models that are too linear to permit the practitioner to integrate the physical and psychosocial aspects of man.

If psychiatry is to live up to its capacity for instilling humanistic values in the physician—to prepare him for empathy, rapport, and sensitivity with patients and to integrate the physical and psychosocial studies of man—then it must work with the emerging physician. It must speak to the physician in terms he can understand by offering a humanistic, interhuman perspective on patients as a complement to the technological preoccupations of our modern scientific medicine. This issue of the *Journal* carries a number of papers that report new means for educating nonpsychiatric physicians. What is important is the emphasis on the training of the undergraduate medical student. The techniques for teaching the medical student may change or be replaced. The focus of psychiatry on its interface with medicine is basic to addressing the crises of identity, confidence, and direction in the general physician and in the psychiatrist and to defining the relationship of psychiatry to society at large.

BRIEF COMMUNICATIONS

Amnesia and Competency To Stand Trial

BY DENNIS KOSON, M.D., AND AMES ROBEY, M.D.

In case law, defendants suffering solely from amnesia who are otherwise competent to stand trial are generally found to be competent. However, temporary, treatable amnesia may warrant a finding of incompetency. The authors review current concepts of amnesia. They stress the need for the psychiatrist to understand the nature of amnesia so that he may assist the court in its adjudication of competency to stand trial.

WHEN A CRIME OCCURS the courts are committed to bringing the accused to justice as quickly as possible. Justice includes preserving the defendant's constitutional rights, particularly the right to confrontation by his accusers, to consultation with counsel, and to due process in general (1).

The legal concept of competency to stand trial has received considerable attention recently as a result of increasing concern for these constitutional rights. This concept developed, first in common law, then in statutory law, as an extension of the prohibition against trial in absentia. A defendant should be present at his trial not only physically, but mentally as well (2). Most statutes, having codified long-standing common law tests for competency to stand trial, look to the defendant's *present* mental condition to determine whether he has the capacity to understand the nature and object of the proceedings against him, to understand his own position in reference to those proceedings, and to assist counsel in the preparation of his defense in a reasonable and rational manner (3, 4).

The courts face a special problem with respect to trial competency when a defendant claims amnesia for the events of an alleged crime. This problem concerns the amnesic defendant's ability to cooperate with counsel rationally and reasonably. The amnesiac, by virtue of his inability to recall his own whereabouts, the circumstances of the alleged crime, or other events leading up to it, at least theoretically renders himself unable to be of assistance to counsel in the preparation of his defense. If the defendant can neither inform his lawyer of the actual circumstances nor recognize or challenge false or misleading evidence detrimental to his case, should he be found incompetent to stand trial?

To assist the court in making an appropriate determination, the psychiatrist should examine several aspects of the memory defect. Is the inability to remember real or feigned? If it is real, what is its cause? Is it temporary or permanent? If it is temporary, is it treatable? Is it crucial to his case (on psychiatric grounds) that the defendant be able to remember?

A review of case law indicates that defendants suffering solely from amnesia who are otherwise competent to stand trial generally are adjudicated competent. In *State v. McClendon* (5) and *Commonwealth ex rel Cummins v. Price* (6), for example, appellate courts found that the defendants, who were suffering from traumatic amnesia, were competent to stand trial; it was stated that amnesia does not totally incapacitate defense and that the defendant is free to assist counsel in a number of other ways. Nevertheless, in many states there is the suggestion in case law that *temporary, treatable* amnesia may warrant a finding of incompetency (7).

There is ample authority to the effect that competency to stand trial generally includes the faculty of memory (3, 8–11). If this were consistently held, however, any amnesic defendant would have to be found incompetent. Many have not been so adjudicated, and appellate decisions, which clearly distinguish between *temporary* and *permanent* amnesia, seem to be made on the practical basis that an adjudication of a *permanently* amnesic defendant as incompetent precludes forever the possibility of his returning to trial.

As an alternative to an adjudication of incompetency to stand trial, several courts have ruled that defendants suffering from treatable, temporary amnesia should be granted a continuance "to employ such expert assistance,

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this work was done, the authors were both with the Center for Forensic Psychiatry, Ann Arbor, Mich., where Dr. Robey is Director; Dr. Koson is currently a resident in psychiatry, University of Pennsylvania, Philadelphia, Pa. Address reprint requests to Dr. Koson, 236 West Albemarle, Lansdowne, Pa. 19050.

in addition to counsel, as may be required to induce defendant to remember" (12), particularly in the event that "full possession . . . of independant recollection is really essential to the fairness and accuracy of the trial" (13). This tactic does not demand an adjudication of incompetency with resultant adjournment of the trial and commitment of the defendant to a mental hospital.

Since the courts find the distinction between temporary and permanent amnesia of use, it is appropriate to review current concepts of amnesia—in particular, its diagnosis, course, and treatment.

CURRENT CONCEPTS OF MEMORY AND AMNESIA

Memory, in the simplest form of the process, involves taking in information through our senses (input), storing it (memory formation), and at some future time recalling it on demand (output). Input can consist of outside sights, sounds, smells, etc., such as a picture, a string of words, or the odor of bacon. Once the thing to be remembered gains access to the memory system, the process of memory formation takes place. Such input must go through two steps in order to be remembered: a short-term or temporary stage and a long-term or permanent stage.

Short-term memory is what is used when, for example, a telephone number is remembered for a few seconds while being dialed and then is quickly forgotten. This form of memory storage is easily disturbed by such things as interference or distraction. If someone asks a question, we forget the number and must look it up again. Entry to this stage of memory requires normal perception and attention, that is, events must be perceived correctly and be significant or important enough to warrant focusing attention on them. The input will, if it persists in short-term memory, become fixed or registered and become part of the long-term memory store. These permanent memories can then be recalled at some future time on demand (stimulus), a complex and poorly understood process that depends, among many other things, on normal functioning of the brain.

Amnesia is defined here as the inability to recall events that properly "ought to be" recalled, that is, events that are significant and warrant sufficient attention. For instance, we "ought" to remember our children's names, our own telephone number, a criminal act, etc.; failure to do so constitutes amnesia. If we cannot recall someone else's telephone number, what we had for breakfast last week, or a string of words, we are simply forgetting. To put it another way, amnesia can loosely be considered pathological or unwarranted forgetting. Interference at any stage of the process between input and output may result in amnesia.

Causes and Types of Amnesia

Amnesia may be divided into disorders of memory *formation* and *recall*. Any process that interferes with the formation of a short-term memory or its fixation into long-term memory results in a complete or permanent amnesia, from which no recovery is ever possible. It is convenient to refer to this as a *registration* amnesia. Where the memory is presumed to have been formed and stored permanently, but access to it is somehow prevented, the result is an amnesia that in many cases is temporary and treatable. This may be referred to as a *recall* amnesia. Table 1 lists some of the conditions that may cause amnesia and the stages of the memory process at which they may interfere.

Many conditions can affect both memory formation and recall. For example, alcohol-intoxicated people often have difficulty recalling things from the recent past ("Where did I leave my car?") and at the same time have trouble forming new memories of what is happening ("Where did I get that drink?"). Intoxicants that can interfere with long-term memory formation commonly also include other depressants such as barbiturates and tranquilizers when used to excess. Brain damage, too, may impair both memory formation and recall. The most common forms of brain damage are associated with chronic alcoholism, vascular disease, senility, and trauma. Less commonly encephalitis, tumor, epilepsy, and other types of disease will be seen. While certain mental states such as psychosis, sleep deprivation, and severe depression may so impair perception and attention as to prevent even short-term memory, the most dramatic amnesias result from psychological blocking of normally formed memories. Most notable in hysteria and the affective psychosis, and certainly in other disorders and normal people as well, repression may act to prevent emergence of certain painful or anxiety-provoking memories into consciousness. Of the many conditions listed in table 1, only the repressive amnesias and recall amnesia based on acute, *reversible* brain damage are potentially treatable.

While it is not possible to discuss many causes of functional and organic amnesia, several common examples may serve to illustrate some of the diagnostic problems. In a forensic setting, probably the most frequent causes of amnesia are alcoholic blackouts and head trauma. Courtrooms are filled with defendants who committed crimes while under the influence of alcohol or other depressants. As table 1 shows, intoxication with depressants may act at several stages of memory formation by disturbing attention and short-term memory, as well as by preventing registration of long-term memory (14).

Other aspects of the alcoholic blackout may confuse the diagnostic picture. The amnesia associated with the blackout may take several forms. There may be a complete or en bloc total amnesia, as well as a spotty, vague form that may be resolved with recall exercises (15). In the latter form, spotty amnesias may show a thematic pattern, suggesting repression, and many alcoholics have the type of personality and psychosocial functioning that is consistent with such repressive phenomena. Obviously, an adequate history of the extent of intoxication, the amount of alcohol used, any other drugs involved, the effects of habituation, and a psychological profile should be obtained.

No discussion of amnesia in a criminal defendant is

TABLE 1
Examples of Conditions That Interfere with Memory Formation and Recall

Memory Formation (Permanent Amnesia)			Recall (Temporary Amnesia)	
Short-Term Memory (Perception and Attention)	Long-Term Memory (Registration)	Chronic Irreversible Brain Damage	Acute Reversible Brain Damage	Repression
Psychosis	Intoxication	Alcoholism (Korsakoff's syndrome)	Encephalitis	Hysteria
Depression	Brain damage	Vascular disease	Trauma	Psychosis
Sleep deprivation	Electroconvulsive shock therapy	Senile dementia	Intoxication	
LSD	Epilepsy	Tumor		
Intoxication	Protein-synthesis inhibitors			

complete without discussing cranial trauma—the classic "bump on the head"—whether it is self-inflicted, accidental, or connected with overzealous apprehension by the police. Cranial trauma produces disorders of consciousness and memory, the extent of which is related to the severity of the trauma (16). There are two aspects to the memory disorder: amnesia for events preceding the trauma (retrograde amnesia), based on a disturbance of *recall*, and amnesia for the time after the trauma (anterograde amnesia), based on a disturbance of *memory formation*. Genuine retrograde amnesia does resolve itself to a greater or lesser degree with time and recall exercises, although the final residual of amnesia may vary considerably. This amnestic nidus may relate more to personality factors, pretraumatic attentiveness, and the importance of the events forgotten.

Barbizet (17) has pointed out that during the period of resolution of retrograde amnesia, paramnesias (where a patient confuses one memory for another) and confabulation may appear. To further complicate the situation, thematic lacunae or islands of amnesia may persist after resolution, involving amnesia for a particular topic or situation that for the patient is laden with negative affect. These should be regarded as any other repressive phenomena.

EVALUATION AND TREATMENT

In the examples used, considerable diagnostic skill may be necessary to distinguish between functional and organic, temporary and permanent, genuine and feigned amnesia. In reference to feigning amnesia, conscious simulation or malingering is always a possibility in the population encountered by the courts. An unusual or improbable pattern of amnesia, failure of retrograde amnesia to resolve, and self-serving, patchy amnesia, where the remembered items have no significance or tend to support only the defendant's innocence, all tend to suggest malingering.

Generally, in the evaluation of amnesia a thorough history and physical examination, with special attention to the neurological examination, careful review of the facts surrounding the amnesia, and skillful interviewing techniques, are imperative. When the clinical evaluation fails to reveal evidence of organically based, *permanent* amnesia, whether due to disturbance of memory registration or recall, diagnostic inquiry must be directed to the possibility of repressive amnesia. As Freud demonstrated, anybody can block or "forget," whether he is normal, neurotic, or psychotic. Many crimes are so painful or anxiety provoking that even relatively normal people can block conscious recall of the events. There is usually no need to make a diagnosis of a hysterical or psychotic disorder to explain this phenomenon. In equivocal cases it is sometimes helpful to employ special diagnostic techniques and an interview under hypnosis or sodium amytal[1] as an aid in uncovering or "lifting" repressed memories (18). Considerable caution should be used, however, in interpreting the results of such interviews.

The entire question of treatment is too complex for inclusion in this brief discussion of amnesia. By definition, however, the *permanent registration* amnesias cannot be treated. Amnesia due to repression may be lifted with treatment, which may involve psychotherapy, narcosynthesis, hypnotherapy, or, in many cases, simply the passage of time. The value of treatment for those who have repressed a painful memory is not only to restore the memory so that they may be considered competent to stand trial (for, indeed, they may have already been found competent despite the amnesia), but also for another reason. When there is considerable blocking of events surrounding the commission of a crime, sudden introduction of the repressed material into consciousness during the trial process may precipitate an acute psychotic or depressive decompensation in a patient whose level of adjustment was marginal and may seriously compromise or destroy his competency to stand trial. While this factor is not necessarily determinative, it should certainly be considered by the psychiatrist when formulating his initial opinion concerning competency and the effect of amnesia upon it.

The recovery of acute reversible brain damage (typically within a maximum of a few weeks) will usually allow amnesia associated with the events prior to the disturbance to resolve, as well as any anterograde amnesia that occurred. As indicated earlier, some residual am-

[1] At the Center for Forensic Psychiatry we now use the more rapid acting sodium methohexital (Brevital).

nesia may remain, and narcosynthesis may be useful in determining whether this is basically associated with repression or is more permanent in nature. Recall exercises may also be useful in the treatment of an amnesia; these involve repetitive review of the facts by a therapist, obtaining associations, and assisting the amnesiac in making permanent those memories which can be obtained. It of course can be mentioned that one of the most striking recall exercises is the actual trial itself.

CONCLUSIONS

It is obviously difficult to treat so complex a subject as amnesia in so brief and cavalier a fashion. In the past the courts have largely dealt with the issue on the *practical* basis of ultimate disposition of the case and have tended to adjudicate incompetency (or alternatively, grant a continuance) only where treatment was possible. The need for the psychiatrist to have an understanding of the nature of amnesia is obvious, so that he may appropriately assist the court in its adjudication of competency to stand trial. If the forensic psychiatrist can explain to the court "the nature of the beast," he may significantly increase the value of his opinion to the courts, which are struggling with the problem of the criminal defendant who says, "I don't remember."

DISCUSSION

L.C. MAGUIGAD, M.D. (Oxon Hill, Md.)—The issue of competency to stand trial can be a special problem to courts, particularly if they are dealing with a defendant who has a clinical problem that may conflict with established or standard court practices. The case of an amnesic defendant is one clinical example. Because of the complex relationship between law and psychiatry, an adequate solution—namely, to simultaneously serve the clinical needs and to conform with the legal requirements of the defendant—may be difficult if not impossible.

Drs. Koson and Robey attempt to bring to our attention the important subject of amnesia and competency to stand trial, which should generate serious concern not only among forensic psychiatrists in particular, but among all psychiatrists. In their paper they suggest that permanent amnesiacs—those who may never be judged as competent for the rest of their lives—may be a problem for eventual optimum disposition. What should the court do when confronted with an amnesic defendant accused of murder who may never be competent for the rest of his life? In the disposition of such cases some questions arise. Should the defendant stay in a mental hospital for the rest of his life? Should he be released to society with or without supervision? Should he be convicted regardless of the circumstances under which he is tried? Should he be found not guilty by reason of insanity? These are indeed serious questions that may serve as a challenge to psychiatry, and they deserve answers that were not pointed out in the authors' paper.

The closest adequate disposition to the problem in the case law is the case of *United States v. Wilson.* In this case the United States Court of Appeals found it necessary to retry the case because the defendant was found to suffer from amnesia of the alleged offense. The court argued that it would not be fair to convict a defendant if his amnesia substantially reduced his ability to assist counsel in his defense. The courts should be guided by the precedence of this appeal decision: that it would not be fair to try a defendant if, because of genuine amnesia, he is substantially handicapped in his ability to effectively participate in his defense.

At this point it is relevant to remind examining psychiatrists that they have a serious responsibility in carefully appraising an amnesic defendant. In my opinion it is not enough to be aware of the clinical causes and mechanisms of amnesia. Because of the serious implications of our opinions with respect to the amnesic defendant, we should try to effect a high level of diagnostic accuracy. In the forensic setting the matter of malingered amnesia may baffle even the astute clinician. I regret that Drs. Koson and Robey did not elaborate more extensively on this subject. There may be more of an element of malingering in the case of an amnesic defendant than we are willing to accept and are able to recognize.

In our clinical assessment, I think it is also relevant to recognize our subjectivity in our clinical contact with the defendant, which was missed in the authors' paper. Our feelings toward the defendant and his alleged offense, our attitudes toward crime in general, our value systems, and unconscious motivations are some of the many factors that can play a significant role in formulating our opinion about a given defendant, particularly in borderline cases or cases involving unclear diagnostic categories, which can create conflict and confusion in forensic psychiatric practice. A diagnostic adjunct such as the sodium amytal interview, which was suggested by the authors, has questionable value, in my opinion. Theoretically it may dissolve the defenses of a susceptible individual or may mobilize repressed conflict that can overwhelm him to a psychotic state, thus compromising our usefulness.

In essence, at the present stage I agree with the authors that we should mobilize all our clinical resources, combining clinical objectivity, sense of integrity, and sound clinical judgment, in our approach to the problem of amnesia. If we can keep in mind that we are clinicians rather than judges with respect to

the defendant who says, "I don't remember," to an alleged offense, our contributions to the courts can go far, not only to bring simple justice to a particular defendant but perhaps also to increase our effectiveness and value to the courts. I congratulate Drs. Koson and Robey for bringing to our attention a serious and complex problem. I hope that the impact of their paper will pave the way toward specific legislative changes that may simplify the problem of amnesia and competency.

Legal Services as a Tool in Treating the Addict

BY JOYCE LOWINSON, M.D., JOHN LANGROD, M.A., AND LEWIS ALPERIN, LL.B.

Since many patients in methadone maintenance treatment programs have legal problems, the authors suggest that such programs employ an attorney to help them. They discuss the attorney's role in allaying patients' anxieties about the legal system, in guiding them through it, and in educating the courts about methadone maintenance programs. They also present data on the kinds of offenses addicts in their program committed in a one-year period.

IT IS WELL KNOWN THAT MOST ADDICTS support their habits through criminal activities (1, 2). Consequently, many have spent time in jail, either in pretrial detention or following conviction. Many go through a continuing cycle of short-term penalties for possessing drugs or for prostitution; some serve long sentences for armed robbery, burglary, or selling drugs. It is not unusual for an addict to have spent at least as much time in jail as in the community.

Although it is currently fashionable to espouse prison reform, our penal system continues to make rehabilitation accidental (3, 4). Recidivism rates are intolerably high for most prisons in the United States—as high as 80 percent (4).

The addicted inmate is even more likely than the nonaddicted offender to return to a life of crime. Every addict who has been behind bars ruefully tells stories of going from jail "straight to the cooker," and thus to the criminal activity that is involved.

Addicts seeking treatment often have legal problems; therefore, most addiction treatment programs provide some form, however rudimentary, of legal services. If there is no attorney on the staff, a staff member or a successful older patient may accompany the defendant to court to intercede on his behalf. Clients arrested after entering treatment risk discharge from the program and are usually given no assistance. To our knowledge, no program except methadone maintenance has published accurate, reliable records of the outcome of legal services or even of the effectiveness of treatment in eliminating further criminality.

Addicts in methadone maintenance treatment programs (MMTPs) have shown a dramatic decrease in criminality as measured by their rate of rearrest (5). All city and state-funded methadone maintenance programs in New York City report data to the evaluation team at the Columbia University School of Public Health. One of these programs, the Albert Einstein College of Medicine-Bronx State Hospital Methadone Maintenance Treatment Program, has collected its own statistics concerning the extent to which its patients encounter legal problems. This paper will describe the legal services provided by the program in an attempt to resolve these difficulties.

THE PROGRAM LAWYER

It is the conviction of the program staff that to initiate treatment only to have it interrupted by imprisonment is both futile and destructive. To exclude applicants with legal problems would mean that 25 percent of those currently in treatment would have been ineligible. Therefore, in order to guarantee continuity of treatment to those facing imprisonment, the program employs an attorney on a consultant basis to represent them in court. Although it has not been documented, clinical observation strongly suggests that patients respond better to treat-

ment when legal problems and concomitant anxieties are resolved. Psychotherapists should take these reality problems into consideration when dealing with addicts.

Despite public awareness of the value of addiction treatment programs, misconceptions regarding methadone maintenance still exist in many courts. Publications by such persons involved in the judicial process as jurists, attorneys, and probation officers have contributed to the acceptance of MMTPs, although much remains to be done (6–8). Too often lawyers who represent addicts are unfamiliar with methadone maintenance treatment. A program providing legal representation must make certain that its attorney is fully aware of the program's philosophy, methods, and results.

In the past the philosophy of the criminal courts has been to "get the addict off the street." As a result, when addicts appear in court, they are afraid of being remanded. Representation by a lawyer connected with their treatment program relieves their anxiety. In addition, a patient who has a lawyer he trusts is more apt to be truthful with him and consequently with the court.

A staff attorney frees counselors from the necessity of frequent court appearances, thus allowing them to work more intensively with their patients. The lawyer, by submitting monthly legal reports that detail pending cases, new arrests, and evaluation of past cases, assists in monitoring and evaluating the extent and nature of criminality among the patients.

THE STUDY

We examined the records of 1,026 patients, all of whom were in the methadone maintenance program at any time during the 12-month period between April 1, 1970, and March 31, 1971. Of the 599 patients admitted during this period, a total of 150 (25 percent) had court cases pending. Most of their arrests involved charges related to possession of narcotics and to larcenies committed to support addiction. Convictions in these cases would ordinarily result in prison terms for the defendants; however, defendants in the program who are represented by the program attorney are rarely imprisoned.

If the patient is likely to be found guilty, the lawyer seeks to obtain a reduced sentence by having him plead guilty to a lesser charge that will result in more lenient treatment by the court. The presiding judge is informed of the defendant's treatment in the methadone program, and a letter written by a program counselor describing the defendant's progress is submitted to the court. The judge may sentence the patient to a conditional discharge, which is, in effect, a suspended sentence. In other instances, the judge will adjourn the case and request additional progress reports. The court expects continuation in treatment; while the defendant who receives a conditional discharge is free of any obligation to the court, the defendant whose case is adjourned is under further legal obligation and must report to the probation department where presentence reports are prepared for presentation to the court. Most reports are favorable, reflecting the fact that the defendant is in treatment.

Occasional difficulties have been encountered; for instance, the investigating officer may not look farther than the defendant's record prior to treatment, or he may feel that a patient who has failed in a drug-free program is likely to fail on methadone. In cases like these it is the lawyer's role to convince the court of the effectiveness of the MMTP. Despite some difficulties, of the 150 cases handled during the 12-month period, no methadone patient charged with a misdemeanor committed before his entry to the program was sentenced to prison.

Patients entering the program who have been charged with a felony require additional effort. For example, a defendant charged with armed robbery is more likely to be imprisoned than a misdemeanant even though he is in treatment. During 1970, however, only two felony cases drew jail sentences. The first, not handled by the program's attorney, resulted in a one-year sentence because a shooting was involved. The second patient was tried in federal court, and sentenced for violation of probation because his rehabilitation was unsuccessful. All other felony cases resulted in favorable dispositions. Indeed, notable successes have been achieved with patients having lengthy prior records.

It is not uncommon for a patient entering the program to have a bench warrant issued when he failed to appear in court following release on bail or on recognizance. Since there are nearly 80,000 outstanding bench warrants

TABLE 2
Distribution by Category and Disposition of 86 Charges Against 64 Patients Arrested While in the MMTP

in New York City, a patient who has failed to appear may not be apprehended for some time (9). The procedure the program follows in such cases is to permit the patient to receive treatment for approximately one month before surrendering himself to the court. The patient agrees, having been assured of legal representation. When he does appear in court, he is usually paroled or his bail is reinstated. An effort is made to obtain a final disposition when he surrenders so that the case can be closed. It has been our experience that as long as the court is aware of the patient's progress in treatment, he will not be remanded.

Resolution of warrants is an important part of rehabilitation. Should the patient be arrested, even for the most minor violation, or by mistake, the outstanding warrant may cause him to be incarcerated without bail for several days, thus interrupting continuity of treatment in the community. The patient is made aware of this so that he realizes the risk of concealing outstanding warrants. Answering warrants fosters a sense of responsibility in patients, relieves them of an important source of anxiety, and thus assists them in breaking with the past.

ARRESTS AND DISPOSITION

Although reduction of criminal activity among the patients as a group is considerable, not all patients are able to make a completely successful adjustment even though they no longer have to acquire heroin. During the 12-month period, 64 (six percent) of the 1,026 patients were arrested a total of 86 times. The charges involved are given in tables 1 and 2. One-third (33.7 percent) of the charges were for offenses against property and about 38 percent for offenses involving narcotics and/or marijuana. Two-thirds were for misdemeanors and one-third for felonies. Seventeen percent involved violent crimes such as assault, homicide, or possession of weapons.

Clinical observations concerning the behavior patterns of arrested patients suggest that those who do not have jobs or who derive their livelihood from criminal activities are more likely to be arrested for crimes against property, while those who abuse alcohol or barbiturates are more likely to be arrested for crimes of violence. There appears to be a higher incidence of arrests for possession of drugs among those who associate with drug users than among those who do not.

Patients arrested for misdemeanors usually received representation provided by the program. Most cases ended favorably. The courts have come to understand that, although our program is not always immediately successful, the more time that is alloted to us, the greater the opportunity for rehabilitation. Several patients insisted that they were innocent, and their cases went to trial. In nine out of ten cases, they were acquitted.

CONCLUSIONS

Providing assistance in dealing with legal problems is an important aspect of rehabilitation. In order to render optimal service to patients, we have a number of suggestions.

1. A centrally located legal office in the immediate vi-

cinity of the courthouse would help improve the efficient delivery of legal services and would provide an opportunity for court personnel to learn about the MMTP.

2. Because of the large volume of narcotics cases handled in the courts, it is essential that court and law enforcement personnel be aware of the methadone program and its potential. Comprehensive training seminars about addiction treatment should be instituted.

3. Although many patients are involved in civil suits, such as divorce and custody proceedings, legal assistance is currently confined primarily to criminal cases. Many patients have been denied their civil rights. Ex-addicts and individuals with criminal records often have difficulty obtaining any form of licensing. Our patients have been refused teaching and driver's licenses, and others have had licenses revoked when they volunteered information concerning past addiction or methadone maintenance treatment. Methadone patients are victims of employment discrimination. An unfortunately large percentage of employers refuse even to consider an ex-addict for employment no matter how well he has adjusted to treatment or how highly recommended he is. Thus, many patients discover that it is difficult or impossible to find any livelihood, much less a satisfying one. Such experiences are traumatic. These situations could be remedied, at least in part, through strong action in the courts, whether through pleading individual cases or through class action.

4. We also recommend the provision of comprehensive legal services, including assistance in both criminal and civil matters, for all patients in drug treatment programs.

Computer Assignment of Psychotropic Drugs

BY IVAN W. SLETTEN, M.D., HAROLD ALTMAN, M.D., M.P.H., RICHARD C. EVENSON, PH.D., AND DONG WON CHO, PH.D.

Data on drug assignment from patients' case records were used to: 1) derive a computer formula for assignment to one of three major drug categories, 2) compare the results from this formula with those from a previous formula using prototype data, and 3) determine the agreement between this formula's results and the drug assignments made by the patients' physicians. The authors conclude that the computer can regularly suggest assignment to one of three major drug categories, although the clinician will still have to make the final decision.

THE MISSOURI DIVISION OF MENTAL HEALTH has a statewide computer network called the Missouri Standard System of Psychiatry (SSOP). In this system extensive clinical information is keypunched from checklist forms on patients cared for at hospitals and clinics. The data are teleprocessed to the computer at the Missouri Institute of Psychiatry in St. Louis (1).

A central goal of the system is to use the data collected to develop computer-based statistical models of psychiatric conditions. When such models are compared with data on individual patients processed in this system, one is able to classify the patient and generate predictions and probability statements about that patient's behavior and outcome. The accuracy of such statements based on the use of statistical methods has been repeatedly compared with the clinician's accuracy. It has been found that the

*Agreement = 60.5 percent.

statistical actuarial approach is as accurate as or more accurate than the clinician (2–4). Thus it seems likely that the clinician will benefit from such statistical predictions as he makes his own final clinical decisions (which are predictions) about his patients. Using the Missouri Computer System, the SSOP, and the actuarial approach, we now provide probability statements to the clinician concerning diagnosis, elopement, length of stay, and suicidal and assaultive ideation (5–7).

Since psychotropic drug treatment is based at least in part on mental status findings, we are attempting to develop a system in which the computer can use a set of statistical equations to assign drug treatment for patients on the basis of the patients' mental status findings. Our aim is to provide clinicians with reasonable suggestions about appropriate drug assignment for their patients as soon as they provide the computer with mental status data about the patients.

In our first study (8), 33 senior clinicians in the Missouri Division of Mental Health were asked to indicate those items on our 111-item standard mental status checklist form (9) for which they thought each of ten psychotropic drugs was particularly effective. The ten drugs selected were five major tranquilizers (chlorpromazine, trifluoperazine, thioridazine, fluphenazine, and haloperidol), three minor tranquilizers (chlordiazepoxide, diazepam, and hydroxyzine), and two antidepressants (imipramine and amitriptyline). These ten drugs are officially recommended by the Missouri Division of Mental Health superintendents. Although agreement among clinicians was found to be low for the ten individual drugs, it was found to be good for the three major drug groups. Using these clinicians' mental status ratings and the drugs recommended for each of the mental status profiles, we were able to develop a statistical formula. This formula, when applied to the same data, was able to assign the drug group to each mental status profile in 84 percent agreement with the rating clinician's original drug assignment (on cross-validation). This study gave us a formula for the clinical conceptual prototype concerning which type of drug should be used for which symptoms.

The aim of a second study (10) was to validate with videotaped interviews the formula derived from the first study. Twenty mental status interviews with patients were videotaped. Staff and resident psychiatrists throughout the division viewed sets of these videotaped interviews and filled out the usual mental status checklist and diagnosis form for each interview. In addition, the clinician was asked to indicate the drug of choice (from among the above ten) or to indicate that no drug be prescribed. From 21 to 33 psychiatrists rated each of the 20 interviews and a total of 500 ratings was obtained.

Since the statistical formula developed in the first study made no provision for a "no drug" assignment, two analyses were made of the videotaped data. The first omitted all "no drug" assignments made by the clinicians, resulting in 67 percent agreement between the formula and the consensus of the clinicians rating the videotaped interviews. It was noted, however, that the computer typically assigned "no drug" patients to the minor tranquilizer group. The similarity between patients receiving minor tranquilizers and those receiving no drug has also been noted by Overall and associates (11). In the second analysis, we assigned "no drug" patients to the "minor tranquilizer" group, and an increase in agreement to 75 percent was noted. In this second analysis, the computer, using the statistical formula from the prototype data, agreed with the clinical consensus about as well as the clinicians agreed among themselves (77 percent).

In the study to be reported here, actual drug data from patients' case records were used. Our aims were: 1) to derive a discriminant function formula from these data for the three major drug categories, 2) to compare results using the formula from actual patient drug data with the formula developed in the study using the prototype data, and 3) to determine the agreement between drug assignment by the formula derived from these actual data and the drug assignment made by the actual clinicians in the field.

METHOD

Inpatients from four Missouri Division of Mental Health facilities were studied. If the patient had had the automated standardized mental status examination (that used in the above studies) and if he had been assigned by his physician to one of the ten above-mentioned psychotropic drugs, he was included. There were 6,477 patients who fitted the criteria. They were then assigned to one of the three major drug categories—major tran-

TABLE 2
*Validation Sample from Actual Patient Data (N = 3,250)**

Assignment by Responsible Clinician	Assignment by Discriminant Function Formula		
	Major Tranquilizers	Minor Tranquilizers	Anti-depressants
Major tranquilizers	1,234	461	337
Minor tranquilizers	149	500	155
Antidepressants	103	98	213

*Agreement = 60.0 percent.

TABLE 3
Mental Status Items That Best Discriminate Among the Three Drug Groups

Rank	Item	Assignment
1	Doesn't know why hospitalized	Major tranquilizer
2	Mood depressed	Antidepressant
3	Flat affect	Major tranquilizer
4	Shows silliness	Major tranquilizer
5	Inability to understand proverbs	Major tranquilizer
6	Delusions of persecution	Major tranquilizer
7	Sad facial expression	Antidepressant
8	Fragmentation of thinking	Major tranquilizer
9	Guilt feelings	Antidepressant
10	Motor activity decreased	Antidepressant
11	Clothing and hygiene poor	Major tranquilizer
12	Speech excessive in amount	Major tranquilizer
13	Suicidal thoughts	Antidepressant
14	Perseveration	Major tranquilizer
15	Slow verbalization	Antidepressant
16	Delusions of worthlessness	Antidepressant
17	Expressionlessness	Major tranquilizer
18	Unrealistic hostility	Major tranquilizer
19	Impulsive acts	Minor tranquilizer
20	Insight and doubt about hallucinations	Major tranquilizer

quilizers, minor tranquilizers, and antidepressants—depending on which of the ten drugs they had been assigned to by their physicians. These patients were alternately assigned to a derivation and a validation sample. A discriminant function formula was developed from the derivation sample. It was then used on the mental status profiles of patients in the validation sample to assign the patient to one of the three drug categories. The drug assignments made by the statistical formula were compared with the drug assignments actually made at the outlying hospitals by the clinician caring for the patient. Agreements were then calculated between the computer formula and the clinician.

These same discriminant functions derived from these actual patient drug data were also applied to the data from the earlier, videotaped study. In the videotaped study, the consensus of all the clinicians rating that interview was used as the criterion.

RESULTS

Tables 1 and 2 show the results of applying the discriminant function formula developed from the actual patient data to the mental status ratings of these actual patients. For the derivation sample the agreement between formula and clinician was 60.5 percent and for the validation sample it was 60 percent. This agreement is somewhat lower than the 75 percent agreement between clinician and computer obtained with the videotaped data using the prototype formula. This may be the result of having to use a less valid criterion of drug assignment in the actual drug-data validation, in which we have the opinion of only one clinician, than in the videotape validation, in which a consensus of raters' opinions was used. It may also have resulted from the fact that the videotaped patients represented a sample of patients easier to classify in terms of drug assignment than is the average patient seen by the clinician.

Other problems with the actual patient data were that patients were sometimes receiving more than one drug, which would indicate a mixture of symptoms, and that the mental status reports may not always have been completed at precisely the same time that the drug assignment was made. In either case the formula, whether derived from actual or prototype data, produced results when applied to the videotaped data that agreed with the clinical consensus found in the videotaped data (i.e., 74–75 percent) approximately as well as the clinicians agreed among themselves (i.e., 77 percent) when they rated videotaped interviews.

Comparison of the 60.5 percent agreement for the derivation sample with the 60 percent agreement for the validation sample indicates that the discriminant function is extremely stable. This stability results from the large sample size used in deriving it and the high ratio of the number of subjects—3,227—to the number of mental status items—20—used in the functions.

Table 3 shows the 20 mental status items used in the discriminant functions validated in this study. They are ranked in the order in which the stepwise discriminant function program (12) used to derive the formula entered them into the equations. They are listed in decreasing order of their ability to determine assignment to one of the three drug categories.

Table 3 also indicates which items are correlated with the patient's being assigned to one of the three drug categories. These findings help clarify how practicing psychiatrists proceed as they make decisions about the type of drug to give a patient. For example, in table 3 it is noted that in the presence of psychotic symptoms clinicians assign the patient to a major tranquilizer, that if depressive symptoms are present they assign an antidepressant, and that if neither psychotic or depressive symptoms are present they assign a minor tranquilizer.

Clinician Agreement

We derived the percentage of agreement among clinicians for each of the 20 interviews. Also, we derived the percentage of agreement between the consensus of the raters for each of the 20 videotaped interviews and the computer formula derived from actual data. These two types of agreement were correlated to see what effect the level of clinical agreement had on the formula's accuracy in making drug assignments. The correlation was .47.

This correlation leads one to conclude that the agreement between computers and clinicians tends to decrease as clinical agreement decreases. The lack of agreement among clinicians limits one's ability to derive statistical formulas that work precisely—in this case, to assign drugs in agreement with the clinician. If clinicians do not agree among themselves, then one cannot get the computer formula to agree with them.

Comparison of Formulas

Using the formula derived from actual patient data on the videotaped interview data, an agreement of 74 percent was noted with the consensus of the videotape raters. This agreement is similar to the 75 percent agreement on the videotaped data using the formula derived from the clinical prototype data. The sets of functions from the prototype data and the actual data would therefore seem to be about equally accurate. This is not, however, a measure of whether they assign patients to drug groups in an identical manner. A better measure of that is the correlation between their agreement for the 20 interviews (i.e., do they assign drugs in the same way?). The correlation coefficient of .62 suggests that the disagreement between the two is fairly large. This is also suggested by the fact that only four of the 20 mental status items appearing in the discriminant functions derived from actual data also appear among the 20 items in the functions derived from the prototype data, and by the fact that, of the items which are the ten best discriminators for each of the two types of data, there is an overlap of only one item. One is led to the conclusion that the similar accuracy but rather dissimilar mode of operation of the two sets of functions should cause them to complement one another, so that, if they were used in conjunction, a level of accuracy could be obtained that would be greater than for either used alone.

CONCLUSIONS

The various indices of agreement between clinicians and computer formulas presented here are encouraging. It seems likely that drug assignment can regularly be suggested by the computer in terms of probabilities concerning which of three groups of drugs the patient would likely receive if he were treated by a clinician in the Missouri Division of Mental Health. Our plan is to provide such suggestions to our clinicians using our computer and teleprocessing systems. The clinician will continue to make the final decision on drug assignment, but he will have the benefit of knowing what other clinicians would probably prescribe. Other considerations the clinician must make before deciding on a drug for a patient relate to the side effects, allergic reactions, and a patient's past therapeutic responses to particular drugs.

The next, and most challenging, step will be to correlate patient drug treatment with actual changes in symptoms and community adjustment in order to study drug effectiveness on a state-wide basis.

Use of Alcohol by Addict and Nonaddict Populations

BY BARRY S. BROWN, PH.D., NICHOLAS J. KOZEL, M.S., MARILYN B. MEYERS, M.A., AND ROBERT L. DUPONT, M.D.

The authors studied the use of alcohol by a sample of narcotics addicts (N=140) and by a sample of nonaddict nonalcoholics (N=100). They found that the addicts' use of alcohol prior to their use of heroin significantly exceeded that of the normal sample. However, the addicts' use of alcohol decreased as they became involved with heroin and did not increase during treatment.

THE ABUSE OF ALCOHOL BY NARCOTICS ADDICTS has become a cause for concern among many members of the narcotics treatment community. Gearing (1) has found that approximately 20 percent of a sample of methadone maintenance patients discharged from a program had been discharged as a consequence of alcohol abuse. Earlier studies (2–4) reported the addict as having been a relatively heavy drinker prior to his use of drugs, thereby establishing a basis for later difficulty with alcohol. Most studies that have examined patient performance after treatment has been initiated reported relatively little alcohol abuse while the patient remained in treatment (5, 6), but significant alcohol abuse after the patient graduated from treatment (7, 8). However, one study of posttreatment performance found little evidence of alcohol abuse although its subjects had dropped out of treatment (9).

One problem with which these studies have had to contend is the absence of detailed information regarding addicts' alcohol intake both before and after treatment has been initiated. Moreover, basic research comparing the addict's use of and experiences with alcohol with those of his nonaddict peers is similarly not available.

In order to learn the extent to which difficulties with alcohol may pose a problem in rehabilitation efforts, a study was designed that would permit a full description of alcohol use by an addict sample. At the same time it was decided to broaden the study to permit comparison of alcohol use by addicts with that by nonaddicted nonalcoholics.

The authors are all with the D.C. Department of Human Resources, Narcotics Treatment Administration, 613 G St., N.W., Washington, D.C. 20001, where Dr. Brown is Chief, Bureau of Research and Development, Mr. Kozel and Ms. Meyers are Research Associates, Bureau of Research and Development, and Dr. DuPont is Administrator.

The authors wish to thank Dr. Sami A. Khoury, D.C. Community Health Services Administration; Dr. Dorothee F. Mindlin and Ms. Doris S. Bradley, D.C. Mental Health Administration; and Ms. Josephine C. Brewton, Opportunities Industrial Center, for their cooperation and assistance in making this study possible. They also wish to thank Ms. Barbara Tatham for her help in interviewing the subjects.

METHOD

Two populations were selected for study: 1) an addict group drawn from the patient population of the D.C. Narcotics Treatment Administration (NTA), and 2) a nonaddict, nonalcoholic group drawn from the D.C. Opportunities Industrial Center. Each of the samples was then divided into male and female groups. The final samples obtained were as follows: 1) a male patient-addict group (N=90); 2) a female patient-addict group (N=50); 3) a male nonaddict, nonalcoholic group (N=50); and 4) a female nonaddict, nonalcoholic group (N=50).

The two male samples did not differ significantly in age, education, marital status, race, and current employment. The two female samples were similarly equated.

Almost all of the addicts sampled (89 percent) were receiving methadone and were being counseled. The remainder (N=16) were enrolled in the detoxification-abstinence program. The entire sample of addicts being studied had been in treatment for an average of 5.08 months.

All individuals selected for study were given structured interviews designed to elicit information about their normal intake of alcohol, and in the case of the addicts, their intake of alcohol prior to and during their use of heroin. Additional questions were asked regarding the subjects' past functioning and the impact of alcohol on their social and vocational functioning.

RESULTS

All quantities of alcohol were converted to ounces. Using analysis of variance techniques, comparisons were made of the amounts the patients consumed before, during, and after their use of heroin. As shown in table 1, the use of alcohol generally declined after heroin use began, although this decline achieved significance for both sexes only for reports of hard liquor consumption ($F=5.52$, $p<.01$). Among men there was also a significant difference in wine consumption before and after addiction ($F=3.93$, $p<.05$). In addition, a difference in wine consumption was found between men and women; men consumed greater quantities of wine than women ($F=4.93$, $p<.05$).

TABLE 1
Means and Analysis of Variance for Alcohol Use Before, During, and After Addiction

Period of Use	Wine		Beer		Hard Liquor	
	Percentage	Mean Ounces	Percentage	Mean Ounces	Percentage	Mean Ounces
Before addiction						
Men	64	43.36	84	120.30	69	18.07
Women	48	3.62	82	96.35	72	9.75
During addiction						
Men	47	22.95	54	54.01	20	1.18
Women	28	10.87	50	65.06	10	3.87
After addiction						
Men	37	9.88	53	59.80	31	2.33
Women	24	9.14	58	98.28	26	5.56

As also indicated in table 1, the number of addicts consuming alcohol decreased after they began using heroin. This was true for both men and women and for all alcoholic beverages studied. Again, this decline was greatest for the consumption of hard liquor. The number of those consuming alcohol remained relatively stable from the period of heroin use to the period following treatment when heroin was no longer used. There were some relatively small increases in the number of persons using hard liquor from the period of heroin use to the post-heroin-use period.

Differences were explored between alcohol consumption by addicted men and by the nonaddicted, nonalcoholic men (i.e., normal men). Comparison was made between addicts' preheroin rates of alcohol use and the normal individuals' rates of alcohol use. Results of this analysis are shown in table 2.

The amounts of alcohol consumed by male addicts were consistently greater than the amounts consumed by the normal male group. However, the addicted men differed significantly from normal men only in wine consumption ($t=2.08$, $p<.05$).

A comparison was also made between addicted women and normal women. Here again, the addicts consumed consistently greater quantities of alcohol than the normals. These differences between the groups of women achieved significance for both beer ($t=3.66$, $p<.01$) and hard liquor ($t=2.60$, $p<.02$).

Differences between addicts and normals also appeared in their reports of the difficulties they encountered as a consequence of excessive drinking. As shown in table 3, differences between normal and addicted men were somewhat greater than those between normal and addicted women. While the differences between the addict and normal samples were not great, they were clearly consistent in that the addicts reported a greater frequency of problems associated with excessive alcohol use.

DISCUSSION

Two findings from this study suggest that alcohol has the potential to become a drug of abuse for at least some addicts. On the one hand, addicts' use of alcohol during the period preceding heroin addiction was significantly greater than that by a comparable group of normal, i.e., nonaddicted, nonalcoholic persons. Moreover, addicts, as compared with normals, reported a greater frequency of alcohol-related problems in their functioning in the community. Thus the addicts constituted a group that showed a tendency to make excessive use of particular drugs available to them. For some unknown reason with these individuals the drug of choice became heroin. Consequently, one might anticipate that one unforeseen outcome of treatment for heroin addiction could be the increased use of alcohol.

However, this was found not to be the case. The addicts who were studied were in treatment for an average of nearly six months. During this time, they did not report using alcohol to an extent that was dramatically or significantly different from the quantity they used during the period of heroin addiction when we and others (2, 3) found a decline in their alcohol intake. Indeed, the addicted men reported consuming approximately the same quantities of alcohol postaddiction as the normal men; female addicts, however, continued to consume considerably greater quantities of alcohol postaddiction than their normal peers. Nonetheless, there is no simple turn-

TABLE 2
Use of Alcohol by Normals and Addicts

Accidents from drinking	19	11	12	0
Arrests for drinking	36	7	6	0

ing to alcohol as the addict turns away from heroin.

In this study two factors may have been at work to limit the degree to which alcohol was abused after treatment was initiated. On the one hand, no effort was made to assess separately the rate of alcohol use by addicts who dropped out of treatment. Although the available evidence conflicts (1, 9), it seems reasonable to hypothesize that a larger percentage of dropouts than of retained clients experience difficulty with alcohol. It is likely that the sample of addicts surveyed here (who averaged about six months in treatment) included relatively few potential dropouts. At the same time, it is conceivable that involvement with alcohol is built up gradually over time and that measuring alcohol use among addicts who have been retained in treatment a still longer period would have revealed an increased alcoholic intake. Thus, there is some indication that with increasing time spent in the community, former addicts tend to become more involved with alcohol (4).

Nonetheless, any such speculation must await further study. The data presented here suggest that patients have a potential for alcohol abuse that is not realized as they become involved in treatment. It appears that the patients who remained in treatment recognized the need to control the use of all drugs and that they made efforts to do so. Such efforts may result from counseling or from more purely intrinsic motivations. At this point it would certainly seem unwise for counseling personnel to simply trust intrinsic motivation or the clients' learning experiences. Instead, counselors would do well to recognize that they are dealing with patients whose life-styles have embraced abusing drugs other than heroin and to modify their counseling efforts accordingly.

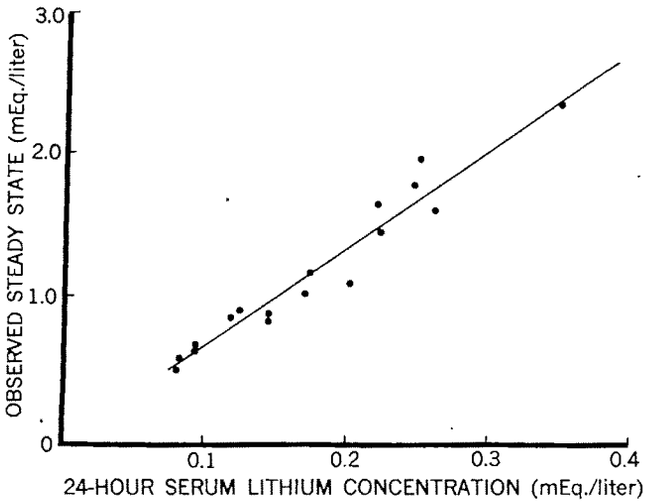
The 24-Hour Serum Lithium Level as a Prognosticator of Dosage Requirements

BY THOMAS B. COOPER, M.A., PER-ERICK E. BERGNER, M.SC., M.D., AND GEORGE M. SIMPSON, M.D.



A technique is described that enables a physician to determine a patient's lithium dosage requirement on the basis of a single blood sample collected 24 hours after the administration of a 600 mg. priming dose of lithium. The authors discuss the basis of this technique and emphasize the importance of ascertaining that the patient has ingested the priming dose of lithium.

THE INTRODUCTION of lithium in the treatment of manic-depressive illness has necessitated the careful monitoring

The authors are with the Research Center, Rockland State Hospital, Orangeburg, N.Y. 10962, where Mr. Cooper and Dr. Bergner are Chief Investigators and Dr. Simpson is Principal Research Psychiatrist.

This work was supported in part by Public Health Service grants RR-05651 from the Division of Research Resources, National Institutes of Health, and MH-03240 from the National Institute of Mental Health.

FIGURE 1
Correlation of 24-Hour and Steady-State Serum Lithium Levels***

*Patient received 600 mg. Li-T.I.D.
**The least-square equation is: steady state = 6.8 (24-hour level) –0.02.

of plasma levels to guard against toxicity. The large interpatient variability in the daily dosage required to achieve a therapeutic level of the drug can lead to a patient's being given too little medication for a considerable period of time before a satisfactory regimen is instituted. At our research center we have patients receiving less than 600 mg. of lithium per day and others receiving more than 3 gm. per day with comparable plasma levels.

We have investigated the possibility of determining a dosage schedule for each patient using a pharmacokinetic approach (1). Data on single-dose responses were collected by giving patients 600 mg. of lithium and then collecting blood samples at one, two, three, four, six, eight, and 24 hours after this loading dose. Using this technique we can accurately predict an individual patient's dosage requirements. However, this approach involving multiple blood samples has little applicability to an outpatient population.

During the past year, all patients requiring lithium treatment were first given a loading dose and, from analysis of these data, predictions were made of their dosage requirements. To date we have completed more than 25 such kinetic determinations and have searched for a less complicated method of predicting dosage requirements

METHOD

The serum lithium determinations were carried out utilizing a Perkin-Elmer Model 303 Atomic Absorption Spectrophotometer fitted with a three-slot Boling burner head. Dilutions of the serum were made with deionized distilled water and the standards were matched for viscosity and electrolyte content by dilution with a known lithium-free serum. As an additional check, the standards were also diluted with six percent dextran in saline solution. This method has been used for several years in our laboratory and has been found to be highly reproducible with a coefficient of variation of less than 1.0 percent.

Patients were given 600 mg. of lithium carbonate followed by 100 cc. of water. The blood samples were then collected on the time schedule described above. Any deviations from this schedule were noted, that is, all blood samples were collected within two minutes of the stated time or a record was made so that the data points could be plotted at the correct time. The serum was then analyzed for its lithium content and a graph of the data obtained was analyzed using a computer technique described in our earlier study (1).

RESULTS

During the investigation described above, it became clear that the level obtained 24 hours after the priming dose was certainly, at the intuitive level, a good indicator of those patients for whom the standard drug regimen would not be satisfactory. To check this further we have run correlations between the 24-hour serum lithium level after a single priming dose and the steady state later achieved for each patient. A very high correlation was found ($r = .972$). On reviewing all our kinetic data it is clear that we can, with confidence, recommend a dosage regimen for a patient from a single blood measurement collected 24 hours after 600 mg. of lithium has been administered. Figure 1 shows the actual data with the line of best fit. Table 1 shows the recommended dosages for patients in various ranges of serum levels after the priming dose.

DISCUSSION

We feel that this technique may be of considerable

TABLE 1
*Dosages Required to Achieve a Serum Level of 0.6–1.2 mEq./liter**

24-Hour Serum Level After Single Loading Dose	Dosage Required
Less than .05	1200 mg. three times a day
.05–.09	900 mg. three times a day
.10–.14	600 mg. three times a day
.15–.19	300 mg. four times a day
.20–.23	300 mg. three times a day
.24–.30	300 mg. twice a day
More than .30	300 mg. twice a day**

*The regimen selected minimizes fluctuation in the plasma level while maintaining a schedule the patient can adhere to. Variation in this regimen can be made at the choice of the clinician, but the total daily dose must remain the same. All "steady state" values are collected just before the next medication is to be taken.
**Use extreme caution.

value for the hospitalized patient who requires lithium treatment, especially in the manic phase. The high cost of hospitalization could be reduced for at least some of the patients who require larger than normal doses of the medication. In an outpatient setting, the patient could see the psychiatrist on one day, be given the medication, and then have a blood sample taken by a nurse or at the laboratory 24 hours later. Treatment could commence from that point, before the analysis had taken place, but the psychiatrist would have the additional information within 24 hours, i.e., whether he was giving a dosage that was either too high or too low.

A word of caution is necessary in the application of this technique. All of the above data are based upon the lithium determinations, and these were carried out in a single laboratory in which the importance of the accuracy of these determinations is fully appreciated. It is recommended that anyone applying the information in these tables do so with care until he determines that the laboratory to which he is sending the serum for analysis is dependable. It is not unreasonable to ask that lithium levels be accurate to the second decimal point.

A recent extensive study (2) of the treatment of acute manic patients with lithium indicates that the optimum therapeutic level of therapy is 0.9–1.4 mEq./liter. However, many authors argue about this so-called therapeutic range (3). We do not wish to enter into this particular disagreement and for this reason we give a regimen designed to achieve a level of 0.6 to 1.2 mEq./liter. In addition, any patient who has a 24-hour serum level (after the single priming dose) greater than 0.3 mEq./liter should be treated with extreme caution. To date we have had only one patient who required less than 300 mg. twice a day to achieve serum levels of 1.2 mEq./liter. Any patient who has a 24-hour plasma level of 0.5 mEq./liter must be regarded as having taken more than the standard dosage of medication, either by obtaining medication from other patients or by having accidentally been given extra medication in the hospital.

It is of course essential that care be taken to ascertain that the patient has ingested the priming dose of lithium. We routinely insist that each patient drink at least 100 cc. of fluid after taking the medication and that the patient be observed for a period of 15 minutes.

Piperacetazine and Chlorpromazine: A Comparison

BY ALONZA C. JOHNSON, M.D., AND A.S. KULKARNI, M.D., PH.D.

Twenty-six agitated acute schizophrenic patients in a state hospital received intramuscular injections of either piperacetazine or chlorpromazine. Three rating scales were used to assess the effects of the drugs. Both drugs were found to be effective in producing significant improvement in the patients. Piperacetazine appeared to be more potent than chlorpromazine. No side effects were observed.

A RECENTLY PUBLISHED REPORT presented a comparative evaluation of piperacetazine (Quide) and chlorpromazine in their injectable forms, using outpatients in a private psychiatric practice as subjects (1). Piperacetazine was found to be an effective treatment for the control of acute schizophrenic patients. This paper deals with a similar comparison of these two antipsychotic drugs, using schizophrenic patients in a state hospital as the subjects.

METHOD

Twenty-six agitated and uncontrollable schizophrenic patients received either piperacetazine or chlorpromazine (Thorazine) by injection. The injections were given as fol-

Dr. Johnson was formerly Chief of Research, Napa State Hospital, Imola, Calif., where this study was performed; he is now Consultant Psychiatrist, Contra Costa County Hospital, Martinez, Calif. 94553. Dr. Kulkarni is Clinical Monitor and Research Pharmacologist, Human Health Medical Department, Dow Pharmaceuticals Research Center, Zionsville, Ind. 46077. Address reprint requests to Dr. Kulkarni.

TABLE 1
Diagnostic Categories, Sex, and Drug Assignment (N = 26)

Diagnosis	Number and Sex of Patients	Assigned to Piperacetazine	Assigned to Chlorpromazine
Schizophrenia:			
Paranoid type	20 males	10	10
Acute episode	2 males	1	1
Catatonic type	4 females	2	2

lows: 1 ml. initially (2 mg. of piperacetazine or 25 mg. of chlorpromazine), followed if necessary by 1 or 2 ml. after one hour and 1 to 4 ml. at approximately four-hour intervals thereafter.

Patients were evaluated prior to each injection on a Target Symptom Rating Scale (0 = absent, 1 = mild, 2 = moderate, 3 = severe) consisting of ten items—pacing, combative, uncooperative, tense, hostile, cursing, disabled, destructive, yelling, and angry. Treatment was stopped when it was possible to initiate oral administration of an antipsychotic drug. A patient not showing satisfactory improvement according to the physician's judgment was termed a "failure." The maximum duration of treatment was 72 hours.

Ratings were also conducted using the Brief Psychiatric Rating Scale (BPRS) (2) and the Clinical Global Impression (CGI) (3). Patients were evaluated prior to and at the end of treatment. Data were analyzed by the Wilcoxon (matched-pairs signed-ranks) test (4) to evaluate both the total improvement and the improvement in each item of the scales shown in each group by the respective drugs. The effect of piperacetazine was compared with that of chlorpromazine by the Mann-Whitney U test (4).

The study was conducted using a "blind rater" system, with the rating personnel blind to which drug the subjects were receiving. The drugs were double-blind labeled and packaged in amber glass vials. Amber glass syringes were used to administer the drug.

The patients' ages ranged from 17 to 48 years. Their diagnostic categories and distribution by sex are shown in table 1. Patients were assigned to one of the two treatment groups using a randomization code. Patients for whom acute alcoholism or drug addiction was a possible cause of their signs and symptoms were not included in the study. We also excluded patients who had, at that time or in the past, any condition that could be aggravated by phenothiazine treatment.

RESULTS

All patients in both groups responded favorably to the treatment and became able to take oral medication. Items in the Target Symptom Rating Scale showing significant ($p < .01$) improvement were: combative, uncooperative, tense, hostile, yelling, and angry for both drugs, and cursing and disabled for the piperacetazine group only. The Target Symptom Rating Scale also showed a significant ($p < .01$) overall improvement for both the drugs.

In the piperacetazine group, 11 patients improved after one injection of 1 ml. and two patients after three injections (a total of 3 ml. per patient). In the chlorpromazine group, six patients improved after one injection (1 ml. each) and seven others received a mean of five injections (a total of 6 ml. per patient).

The total scores for the BPRS were also significantly reduced ($p < .01$) by both drugs. The effects on selected items are shown in table 2. Emotional withdrawal, conceptual disorganization, and unusual thought were reduced significantly by chlorpromazine. The sample size available in the piperacetazine group was too small for these items for a meaningful statistical evaluation. Although anxiety was significantly reduced by piperacetazine and not by chlorpromazine, the difference between the two drugs was not significant (Mann-Whitney test).

The CGI revealed that the drugs did not cause a significant improvement (scores of 6.1 before and 5.9 after for piperacetazine, and 6.0 before and 5.8 after for chlorpromazine). The therapeutic effect in the piperacetazine group was moderate in three patients and minimal in ten. In the chlorpromazine group, a moderate therapeutic effect was seen in six and a minimal effect in seven. Systemic side effects or local reactions at the injection site were absent in these patients.

DISCUSSION

The data obtained from the Target Symptom Rating Scale and the BPRS indicated that piperacetazine and chlorpromazine were about equally effective in controlling the aggressive, acute schizophrenic patients. Animal studies (5) have shown that piperacetazine is up to 50 times as potent as chlorpromazine in certain pharmacological procedures. Therefore, a 2 mg./ml. solution of piperacetazine and a 25 mg./ml. solution of chlorpromazine were employed in this study. An average of 100 mg. of chlorpromazine (4 ml. of 25 mg./ml.) was necessary to control the patients, whereas not more than 4 mg. (less

TABLE 2
Scores on Brief Psychiatric Rating Scale Before and After Treatment

BPRS Item	Piperacetazine Before	Piperacetazine After	Chlorpromazine Before	Chlorpromazine After
Anxiety	4.7	3.9	3.6	3.2*
Tension	6.2	5.2	6.2	4.2
Hostility	5.9	4.5	6.4	3.8
Suspiciousness	5.5	4.5	5.4	3.8
Uncooperativeness	6.2	3.8	6.5	3.3
Excitement	5.9	4.2	6.2	3.5
Total BPRS score	68.6	58.7	62.4	45.9

*Not significant; all other changes are significant ($p < .01$).

than 2 ml. of 2 mg./ml.) of piperacetazine was needed to achieve similar results. This finding supports the greater potency of piperacetazine reported in earlier animal studies (5). Similar differences in potency between the two drugs were found when oral medication was administered to patients (6); the mean daily dose for piperacetazine was 116 mg. and that for chlorpromazine was 647 mg.

The Target Symptom Rating Scale and Brief Psychiatric Rating Scale indicated significant overall improvement in both drug groups. The Clinical Global Impression did not reflect the effectiveness of the two drugs. All patients improved and were manageable enough to permit initiation of oral treatment. Side effects were absent with the two drugs. These findings lead to the conclusion that piperacetazine injection is a useful form of treatment, similar to chlorpromazine injection, in the immediate control of the acute schizophrenic patient.

LETTERS TO THE EDITOR

Contradictions in the Alcoholism Criteria

SIR: The recently published "Criteria for the Diagnosis of Alcoholism" by the National Council on Alcoholism (August 1972 issue) seem to contain a contradiction that I would like to see clarified.

The criteria presented are classified according to various principles; the two classifications that appear to be contradictory are those according to "diagnostic levels" on the one hand and those according to "major" and "minor" criteria on the other. As explained on page 129, "diagnostic level" denotes the certitude with which the given criterion indicates alcoholism: Level 1 is "obligatory" (i.e., a person satisfying this criterion "*must* be diagnosed as being alcoholic" [italics mine]), while level 2 and 3 criteria are only "probable" or "potential" indicators.

Then on page 130 the committee says: "It is sufficient . . . that *one* or more of the *major* criteria are satisfied *or* that *several* of the *minor* criteria in Tracks I and II are present" (italics mine). From this it would seem to follow that all "major" criteria are those of level 1 (and vice versa) and that all "minor" criteria are those of level 2 or 3 (and vice versa). Yet in examining the tables one finds that several major criteria are weighted as 2 or 3, and some minor ones as 1. This leads to the paradox that a person with beriberi "who drinks regularly" (Table 1, Track I, B) should be considered as *possibly* alcoholic, both by virtue of the indicated level 3 weighting and, in my opinion, by the very nature of the case. Yet, at the same time, this criterion alone suffices for the *definitive* diagnosis of alcoholism because it is listed as a major one! Several other examples can be found by examining both of the tables.

Unless we are dealing with typographical errors, it would seem that either the committee committed an oversight or else there is a hidden rationale in these classifications that is not sufficiently explicit, at least for this reader.

In any event, I would appreciate a clarification of this seeming contradiction.

EDMUND F. KAL, M.D.
San Francisco, Calif.

Dr. Seixas Replies

SIR: Dr. Kal's perceptive letter points up an ambiguity in the "Criteria" that we felt to be necessary at the current stage of our knowledge in order to adequately cover some of the difficulties in assessing individual patients for the presence of alcoholism. The "grand design" of the separation into major and minor criteria includes as major criteria items that are indissolubly linked to alcoholism by virtue of the nature of the addiction process. Under this heading comes any physical disease process that originates in the large quantities of alcohol taken by the alcohol-dependent person. Some disease processes might occur fortuitously in a person who also drinks regularly but who is not alcohol-dependent. It is for this reason that a diagnostic level of 2 or 3 was given in some of the disease situations. Should the disease process clearly be the result of the drinking, then there would be no question about the major category and the diagnosis. Thus, the diagnostic level becomes a reminder for diligence in searching for other causes in the disease process.

In the minor criteria one will note in the physical area more in the way of symptoms such as cardiac arrhythmias, which, even if related to alcohol ingestion, would not imply to such a great degree that the addictive use of alcohol was at fault. Thus, anyone who had beriberi related to his use of alcohol and not directly to nutritional difficulty caused by economic factors, etc., should be involved in an alcoholism treatment program. However, if the alcohol use was incidental, there would be no need to involve him in such a treatment program but, rather, to care for his nutritive needs. Therefore, in relationship to alcohol-related diseases the only consideration that decreases the diagnostic level from level 1 to level 2 or 3 is the potentiality of other causes. However, in cases where alcohol-related diseases are definitively associated with alcohol use, we feel that the patient should be entitled to treatment for alcoholism.

This also pertains to the question of the alcoholic blackout; the committee felt that great care was required in separating it from other forms of memory lapse, temporal seizures, or even malingering. A self-report of loss of control over drinking would necessitate similar caution. Among the minor criteria one finds listed two laboratory tests that were placed among the minor criteria for editorial convenience but that are clearly labeled major. The one other minor criterion listed with diagnostic level 1 is the blatant, indiscriminate use of alcohol; whereas this was listed as minor but at level 1 primarily to underline the progressive nature of the condition, it was felt that one observer's view of blatant, indiscriminate use might be another observer's view of moderate use.

I hope that my explanation of this purposeful ambiguity is a sufficient one; we expect that experience in using this on individual cases will provide sufficient clarity for separating those people who will be treated for alcoholism and entitled to the benefits therefore as opposed to those who will remain in the gray area between heavy social drinking and alcoholism.

In a second printing of the Criteria reprints the committee has changed the wording that defines diagnostic levels to read as follows: "*Diagnostic Level 1.* This criterion is clearly associated with alcoholism. *Diagnostic Level 2.* This criterion lends strong suspicion of alcoholism; other corroborative evidence should be obtained." These textual changes, it is hoped, will help in current use of the Criteria.

The Criteria Committee is a continuing function of the National Council on Alcoholism, and we expect to obtain experience ratings based on their use and thus to provide greater clarity in the future. The question raised reinforces the necessity to follow our recommendation regarding diagnosis: "A purely mechanical selection of items is not enough; the history, physical examination, and other observations, plus laboratory evidence, must fit into a consistent whole to ensure a proper diagnosis."

Speaking Out on Jewish Young People

SIR: I am puzzled by Dr. Mortimer Ostow's findings ("The Jewishness of Jewish Young People: A Symposium," November 1972 issue) that young Jews who intermarry are "acting out" and that those who may convert to other religions either are suffering from *pathology* or are simply opportunistic.

Through the years, I have known many people who have done one or the other and have found them to be neither sick nor evil. In converting, some have become Unitarians, many Quakers. Of the latter, it can be said that some of our best Jews are *Friends*.

ROBERT SEIDENBERG, M.D.
Syracuse, N. Y.

SIR: I would like to present another view on "The Jewishness of Jewish Young People: A Symposium" (November 1972 issue).

It was distressing to read Dr. Mortimer Ostow's statements about his concept of the problems of young Jewish people. He states that "few non-Jewish psychiatrists . . . comprehend the nature of the communal pulls, their pervasiveness and depth, and the strength of the historical forces to which young Jews are willy-nilly subject." If this is true, what are the implications? Does he feel a Catholic therapist is the best choice for a Catholic patient, a white therapist for a white patient, a male therapist for a male patient? Or does he feel it sufficient for the non-Jewish psychiatrist to educate him or herself via reading articles such as this one? His failure to spell out what conclusions he wishes to draw from this statement is most serious since it touches upon a fundamental issue in almost any psychotherapeutic situation.

I question Dr. Ostow's statement that the "poor personal motivation" of Jewish young people in institutions of higher learning "subsequently results in their becoming involved in campus protest movements. Often what they are protesting against seems to be, in large part, the pressure to go to school." On the basis of what study or research does he make this statement? If anything, it appears to run counter to some published studies, such as those of Keniston.

I find it particularly offensive that he groups intermarriage as "one of the most common of the distressing forms of adolescent acting out within the Jewish community." Dr. Ostow claims that the various types of intermarriage "betray different degrees of pathology." As a partner in a mixed marriage, I am shocked that a member of the mental health profession calls this pathological per se. To imply that it is healthy for a Jew to marry a fellow Jew and a "problem" or representative of a degree of pathology for a Jew to marry a non-Jew is to imply something that, to my knowledge, has never been adequately researched or documented.

In the absence of any sort of documentation this statement leads one to worry that the author is viewing the world through the colored glasses of a particular brand of Judaism. It behooves the author to identify his own Jewish stance since he obviously has criteria for what constitutes too little Jewish involvement and for what constitutes too much.

I would like to end with a quote from Hartmann and associates:

> To put it concretely: Insight based on psychoanalytic psychology tends to enlarge the cultural area or the number of groups to which one feels linked and toward which one feels responsible; an attitude which can well be characterized by its opposite. To interpret one's own actions predominantly in terms of national character seems to contradict the lesson implicit in psychoanalytic psychology (1, p. 65).

NANCY SIMON
Wayland, Mass.

Dr. Ostow Replies

SIR: M . Simon and Dr. Seidenberg call attention to a sentence in my paper that is carelessly constructed. I mentioned that the term "intermarriage" covers a number of different phenomena that "arise from different origins and different motivations and betray different degrees of pathology." Both of these correspondents and others who have spoken to me personally have understood the sentence to mean that there is always some degree of pathology. When I wrote it, I intended it to mean that the degree of pathology might be anything from zero to severe. I appreciate the opportunity to make that correction here.

My clinical experience with young people, supported by informal contacts and by reading some of the things that they have written, has led me to make some of the other statements that they challenge: namely, that intermarriage has become one of the most common of the distressing forms of adolescent acting out within the Jewish community (I did not say that all intermarriage was acting out); that "formal religious conversion out of the Jewish community into another religious community occurs relatively infrequently nowadays in the absence of gross psychopathology"; and that in the case of campus protest movements many of the Jewish students "are protesting against . . . the pressure to go to school." To support the last statement, let me simply note that among the college-age population, 90 percent of American Jews are in college. It is not likely that all or most of them are really motivated to obtain advanced education.

Dr. Seidenberg also challenges my statement that conversion out of the Jewish community "at other times and places . . . implied opportunism rather than illness." It is a matter of historical record (so far as I know uncontested by any serious students) that throughout history most conversions out of the Jewish community have been undertaken in order to secure business, academic, or social advantage, or in many, many instances, simply to save one's life. I will concede that with respect to the last category the term "opportunism" is grotesquely inappropriate.

Ms. Simon asks a series of important questions in her first paragraph. They are: 1) To what extent is it important that the psychotherapist share the historical, cultural, and ethnic background of his patient? 2) To what extent can knowledge substitute for a shared background? and 3) Can one answer the former two questions in general, or don't the answers have to be different for different traditions? Is it as important, for example, for an American-born and -educated therapist to share the specific ancestral tradition of a member of a family that has lived in the United States for two centuries as it is to share the background of the adolescent son or daughter of Jewish survivors of the holocaust? It was the purpose of my paper to raise such questions and to suggest that they be discussed by my colleagues. At this moment I have no ready answers, and I look

forward to hearing the opinions of others.

It was not my intention to establish criteria for what is a normal or proper amount of Jewishness. It was my intention to point to certain areas of behavior in which Jewish young people seek to resolve their conflicts about their Jewishness. Reverting to the subject of intermarriage, there is a clear and obvious difference in psychic significance between intermarriage for a young Jew whose family has lived in the United States for two centuries and has been intermarrying for several generations and for the son or daughter of a survivor of the holocaust.

The quotation that Ms. Simon adduces from Hartmann and associates puzzles me, for it seems to contrast so sharply with one of the quotations from Freud I referred to in my article. I reproduce it here more fully. In a preface written for a Hebrew translation of "Totem and Taboo," Freud wrote in 1930: "If the question were put to him [i.e., Freud]: 'Since you have abandoned all these common characteristics of your countrymen, what is there left to you that is Jewish?' he would reply: 'A very great deal, and probably its very essence.' "

MORTIMER OSTOW, M.D.
Riverdale, N. Y.

Lobotomies Defended

SIR: Dr. Peter Breggin's Letter to the Editor "Lobotomies: An Alert" (July 1972 issue) may have its value as a warning against the excessive and indiscriminate use of the procedure. His total rejection of lobotomies, however, is as unwarranted as a total rejection of appendectomies just because complications may arise and some appendices have been removed without justification.

I heard Dr. Breggin's paper (1), which was presented to the Fourth International Congress of Social Psychiatry. It was emotional; patients were called clients (apparently Dr. Breggin is an apostle of the Szaszian faith), and in general, one had the impression that he fitted the procedure into a metaphysical rather than a scientific framework. It is of interest that Salter (2), in writing for *Medical Opinion*, had a similar impression of a paper by Dr. Breggin, which was delivered at a conference on violence in Houston, Tex.: "Much of the audience thought he delivered it in a more political than scientific style. It was half-shouted, and bulging with inaccurate J'accuses."

The recrudescence of lobotomies, so deplored by Dr. Breggin, is just an indication of the failure of other methods in intractable cases. The desperate need to help such patients led me to refer two of them to Dr. William B. Scoville for orbital undercutting (3). I was gratified with the results.

Case 1. A 47-year-old female patient underwent orbital undercutting in May 1970 because of a history of continuous depression interrupted by short periods of well-being since mid-adolescence.

There was a history of depression in her family. Her only son committed suicide at the age of 15. Electroconvulsive therapy, administered in 1955, kept her well for about one year. I have been seeing her since 1960. Psychotherapy, antidepressive drugs, environmental manipulation, and occasional hospitalizations for ECT were marked by diminishing returns as time advanced. Life at home was completely disrupted. The husband was in despair, and his life became constricted by the wife's illness.

The patient returned from the operation relaxed and content. Her affect was flat. She slept well. For the first six months or so she felt fatigued and lazy, yet it was a great overall improvement. Interestingly enough, her menopausal symptoms disappeared, and she did not need conjugated estrogens (Premarin) for a period of nine to ten months. Within a year her affect acquired more color. Occasional mild depressive episodes of short duration reoccurred, but they were easily curtailed by the administration of tricyclic drugs.

At the present time, over two years after the procedure was performed, the patient still functions better than before and both she and her husband feel gratified. I could not find reduction of judgment or manifestations of organic brain disease. An EEG taken in November 1971 was normal.

Case 2. A 58-year-old female patient was hospitalized for attempted suicide in early 1950 with a diagnosis of schizophrenia. Following her discharge from the hospital, she had no difficulties until 1965, when her son was found to be a drug addict. She became preoccupied and depressed. She had exhibited an increasingly deepening depression with occasional catatonoid features and a blank, perplexed facial expression since 1967. Monoamine oxidase inhibitors, which were moderately helpful in the beginning, later caused edema, low blood pressure, and dizziness without improving her mood to an appreciable degree. Two series of ECT in a private sanitarium resulted in unremarkable and short-lasting improvement. She lost considerable weight. She looked pale, fatigued, and generally ill.

She was operated on in June 1971. I saw her 12 days after the operation. I then wrote to Dr. Scoville: "The change is remarkable. Her husband says he is highly pleased and that she is as she used to be 25 years ago. Instead of agitation and [a] feeling of emptiness there is contentment and complete relaxation. In fact she seems to be less flat than before."

Like the first patient, this woman was fatigued for about six months. She gained weight and, except for a depression lasting five days a few months ago, her mood has continued to be good. In February 1972, she had a status epilepticus, which was stopped by administering diazepam (Valium) intravenously. A week later her EEG was normal, but she is taking anticonvulsive medication as a precautionary measure. Currently she is content, taking care of the house and babysitting with her grandchildren. Both she and her husband are gratified with the results.

No metaphysical reasoning by professional humanitarians or disruptions of the Houston conference by nonmedical rabble invading the hall (2) will convince me that these two women would have been better off with their suffering than they are at the present time.

EUGENE REVITCH, M.D.
Edison, N.J.

Dr. Breggin Replies

SIR: In his attempt to undermine my criticism of lobotomy and psychosurgery, Dr. Revitch stoops to a personal attack in which he repeats some lies about me and then makes up one of his own. He refers to an article by a colleague of his who quotes me as supporting a leftist demonstration at a recent medical conference, when in fact tape recordings show that I stood up to dissociate myself from the demonstration. Dr. Revitch himself then says that he "heard" my "emotional" speech on psychosurgery at the Fourth International Congress of Social Psychiatry in Israel. Poor Dr. Revitch—no one told him that other obligations called me away from the conference and that I never gave any speech on psychosurgery!

Dr. Revitch also attempts to attack me (while avoiding the issues) by making a slur upon the work of Dr. Thomas Szasz. He is certainly right that I have a great deal of respect for Dr. Szasz, who is the most serious scholar writing in American psychiatry today. Perhaps Dr. Revitch is unable to deal rationally with the straightforward logic and detailed research characteristic of Dr. Szasz's work.

In defense of lobotomy Dr. Revitch again speaks irrationally when he compares lobotomy to an appendectomy. In an appendectomy there is evidence of disease in the organ. In lobotomy there is none. Instead, the normal functioning of the brain is impaired in order to make the person more docile and less human. A more correct analogy to lobotomy would have been the barbaric practice of amputating the genitals to control a sexual problem.

Dr. Revitch's own statements in reporting the case histories indicate that he knows there is nothing wrong with the brain of either one of his patients, and further, that he knows that surgical intervention actually blunts the functioning of the previously normal brain. Thus he baldly tells us, "Her affect was flat," *after* the surgery. He apparently favors a brain-damaged, docile housewife to an anguished, intact human being. The Women's Liberation Movement has been justified in its opposition to the return of psychosurgery.

I also want to point to Dr. Revitch's description of the first patient as an object whom he manipulates in every conceivable fashion—in part to make her less disruptive to her husband. I would also question his judgment in keeping a woman under his treatment for *ten years without success* until, in futility, he mutilates her brain. Since psychiatric treatment depends so much upon personal rapport and other unfathomable factors in the patient-doctor relationship, I would think it imperative to refer such a patient elsewhere long before resorting to brain mutilation.

I have written extensively (20,000 words, 100 references) about the unscientific nature of psychosurgery (1, 2), and I make this material available to anyone who is interested. Suffice it to say, there are *no* controlled data that support psychosurgery, but controlled follow-up studies have uniformly found the patients to be psychiatrically unchanged, except for the addition of surgically-induced brain damage.

In these same references and in my first novel (3), I have analyzed some of the political dangers inherent in psychotechnology; I elaborate on the dangers of psychosurgery in some depth in another novel (4). These political issues became very much alive recently when a group of psychosurgeons went directly to Congress to obtain a million dollars to support their work, which they have publically promoted as a solution to "student," "racial," and "police" violence. A coalition of conservative senators, plus some liberal senators, stood up to resist this threat to the traditional American value of political freedom.

I myself am deeply conservative with regard to psychiatric treatment. I believe that the first injunction is to "do no harm," and that we must never allow ourselves to assault the integrity of anyone's brain, even in the most earnest wish to help. When Dr. Revitch chooses to reduce a person's suffering at the cost of the person's mind, he is close to committing euthanasia—a partial murder of the living human being. No person, however well-intentioned, should take upon himself the power of life and death over another person's mind.

Washington, D.C.

Antinuclear Factor: Age and Sex

SIR: We have read with interest the article "Antinuclear Factor in Psychiatric Disorders," by Dr. Hans von Brauchitsch (June 1972 issue), about the increased prevalence of antinuclear factor in psychiatric patients. Since this is a new and important finding, we believe some features of the work deserve comment.

We know of several large-population studies which have shown that the prevalence of antinuclear antibodies is greater in women than in men and increases with advancing age. Depression is also more common among women than among men and increases in prevalence with advancing age. We are therefore disappointed that Dr. von Brauchitsch did not state whether he took the precaution of matching the control subjects and patients for age and for sex. If this was not done, we suggest that his results may be invalid.

Dr. von Brauchitsch Replies

SIR: The point raised by Drs. Mellsop and Whittingham is well taken. As a matter of fact, I discussed that particular issue in my original presentation of the paper at the 1971 APA annual meeting but omitted it in the final publication for brevity's sake.

The patient sample in my study was too small to allow a meaningful statistical analysis by age, sex, and diagnostic group. It was possible, however, to observe the same trend in the sample as described for the general population. The question that cannot be answered at the present time is whether the higher frequency of positive antinuclear factor reactions in the older female patient group was caused by the fact that the patients were older and women or whether it correlated with the prevalence of depressive reactions in that patient group.

Viet Nam: The Board of Trustees Steps Out of Bounds

SIR: I read with regret the recent resolution by the APA Board of Trustees on Viet Nam policy (July 1971 issue). I expected psychiatrists to have better control of their reaction formations. I believe that their recommendations were unwise as policy, but I do not have the space to go into my reasons.

More important here, I believe that the Board of Trustees should not make such a resolution because it carries the prestige of psychiatry into what I consider an illegitimate area.

The reasoning which says that because psychiatry does have scientific evidence on the effects of war on personality, it may therefore make recommendations about policy on a particular war is untenable (except for strictly psychiatric aspects). To know how best to handle the Viet Nam situation with its global ramifications requires expertise in international relations, political science, economics, military science, etc., as well as in psychiatry (psychology).

If I were to subscribe to the Trustees' reasoning, I could say that since I, as a psychologist, know the effects on personality of various physical diseases, I am therefore competent to prescribe how these physical diseases should be treated and cured. I do not think you would subscribe to this conclusion.

It is my belief that individual psychiatrists may have opinions and even expertise on the complex problems of war and poverty and may speak out like any citizen. But as psychiatrists, and especially as representatives of a prestigious psychiatric organization, they should only make recommendations on strictly psychiatric issues.

Compulsive Water Drinking

SIR: The article "Psychogenic Water Intoxication: A Case Report" by Drs. Michael Devereaux and Ruth McCormick (November 1972 issue) thoroughly describes a highly dramatic medical emergency situation that may occur in psychiatric patients—especially those with schizophrenia. The compulsive drinking of great quantities of water in a relatively short period of time and as a result of delusions was described in Resnick and Patterson's case of a 31-year-old chronic schizophrenic man who claimed that the Virgin Mary had commanded him to drink holy water (1).

Psychogenic water intoxication as a response to delusions also occurred in one of our patients; his case history further corroborates Devereaux and McCormick's findings.

> This patient was a 38-year-old man with a long history of hospitalizations for paranoid schizophrenia and episodic alcohol abuse. Four days before one admission he had begun to hear voices, had become extremely anxious and agitated, and had stopped eating food but had drunk one glass of water after another while pacing the floor. After recovery, he explained that he had had to drink the water in order to prepare himself since he was about to be sucked into the sun.
>
> On the fourth day of excessive water intake he complained of headaches and had gone to bed. An hour later he suffered tonic-clonic convulsions lasting for about ten minutes. Two additional generalized seizures occurred on the way to the hospital.
>
> On admission the patient responded only to painful stimuli and to the gag reflex. His pupils were constricted and fixed. Tendon reflexes were increased bilaterally and the Babinski reflex was positive.
>
> Blood chemistry studies showed the following results: serum sodium—111 mEq./liter, blood urea nitrogen—11 mg./100 cc., potassium—3.5 mEq./liter, glucose—143 mg./100 cc., and bicarbonate [2]—20.5 mEq./liter. The calculated sodium deficit was 1400 mEq./liter. A portable chest X ray showed normal findings. The patient was given 130 mg. of sodium luminal intravenously, and the sodium was very gradually replaced with a 5 percent solution of sodium chloride. Within 24 hours the patient regained consciousness but remained grossly psychotic, requiring high dosages of phenothiazines. He was discharged after three months, and a follow-up examination eight months later showed no recurrence of compulsive water drinking.
